L1-Driven Interference Patterns in EFL Academic Writing: Evidence from Azerbaijani–English Contact

Abstract-This study examines L1-driven interference in the academic English writing of Azerbaijani EFL learners, asking how typological distance shapes morphosyntactic error distributions across proficiency levels. Using a learner-corpus, error-analysis framework grounded in interlanguage theory, we coded article use, prepositions, word order (SOV→SVO), and verb morphology, and modelled patterns by proficiency. Results show systematic, proficiency-sensitive shifts: lower-level writers overproduce morphological deviations (articles, agreement), whereas higher-level writers increasingly display syntactic misalignment (clause-level word order, auxiliary sequencing). Error loci reflect the co-operation of interlingual and intralingual forces, not random lapses. Pedagogically, three high-yield levers emerge: (i) contrastive NP-grammar for definiteness, (ii) pattern-based preposition teaching to replace case/postposition mappings, and (iii) SVO+auxiliary scaffolds for complex clauses. The findings refine accounts of cross-linguistic influence in an agglutinative-to-analytic pairing and offer actionable targets to raise EFL writing accuracy.

Keywords:*Cross-linguistic interference; L1 transfer; Azerbaijani–English contact; Morphosyntax; Error analysis; Interlanguage development; EFL academic writing*

I. INTRODUCTION

Language contact is a central driver of second-language (L2) development, and one of its most systematic manifestations is cross-linguistic interference—the influence of the first language (L1) on L2 performance. In the SLA tradition, interference has been theorized within the construct of interlanguage, which conceptualizes learner language as a rule-governed, evolving system rather than a collection of random errors (Selinker, 1972, pp. 209–212). This view provides a principled way to interpret transfer effects developmentally and to separate interlingual from intralingual sources of error.

A core prediction in transfer research is that the magnitude and loci of interference depend on typological distance between L1 and L2 (Odlin, 1989, pp. 27–31). For Azerbaijani learners of English, this distance is substantial: Azerbaijani, a Turkic language, is agglutinative with a

dominant SOV word order and rich suffixal morphology, whereas English is comparatively analytic/SVO, encoding many grammatical relations via function words such as articles, prepositions, and auxiliaries (Comrie, 1989, chs. 2–4). Typological work thus predicts robust transfer at precisely those form–function interfaces where the languages package the same meanings with different devices—notably in article use, preposition selection versus case/postpositions, auxiliary-supported verb phrases, and clause-level word order (Comrie, 1989, pp. 87–104).

Although prior scholarship has broadly documented transfer phenomena, Azerbaijani–English academic writing remains underrepresented in global SLA corpora, and we still lack a proficiency-sensitive account of how morphological versus syntactic interference evolves as writers attempt more complex, multi-clause discourse. Specifically, it is unclear whether morphology-heavy deviations (e.g., article omission/substitution, agreement) give way to syntax-level misalignment (e.g., SOV→SVO reordering problems, auxiliary sequencing) with increasing proficiency—a pattern suggested by typology and processing accounts but not yet mapped for this pairing (Odlin, 1989, pp. 112–118; Comrie, 1989, pp. 92–104).

To address this gap, the present study conducts a learner-corpus–based error analysis grounded in interlanguage theory, documenting L1-driven morphosyntactic interference in Azerbaijani EFL academic writing and modeling its distribution across proficiency bands. By identifying which error loci persist, diminish, or shift with advancement, we refine transfer accounts for an agglutinative→analytic pairing and propose pedagogically actionable targets: (i) contrastive NP-grammar for definiteness (articles), (ii) pattern-based preposition teaching to "replace" case/postposition mappings, and (iii) SVO + auxiliary scaffolds for complex clauses—interventions consistent with typological predictions and interlanguage development (Selinker, 1972, pp. 223–228; Comrie, 1989, pp. 87–104).

II. LITERATURE REVIEW

2.1 Interlanguage and the status of learner language

The construct of interlanguage reframed learner production as a rule-governed, evolving system, not a set of random errors, establishing a theoretical basis for studying transfer within developmental trajectories (Selinker, 1972, pp. 209–212, 223–228). This view underpins

subsequent methodological choices in error analysis and motivates proficiency-sensitive accounts of change in error profiles over time.

2.2 From classic Error Analysis to contemporary use

Error Analysis (EA) provided a practical pipeline—identification → classification → explanation → interpretation—for investigating systematic deviations in learner corpora and linking them to learning processes and pedagogy (Corder, 1981, pp. 35–41). While early reviews marked EA as a transitional phase, they also documented its enduring value for describing competence and informing instruction, particularly in writing (Richards, 1980, pp. 91–95). In modern SLA, EA persists as a robust, replicable way to map morphosyntactic difficulty loci, especially when paired with corpus normalization and rater reliability.

2.3 Cross-linguistic transfer: scope and mechanisms

Foundational transfer work argues that similarities and differences between languages shape acquisition across grammar, lexis, and pronunciation, and that typological distance modulates the magnitude and loci of transfer (Odlin, 1989, pp. 27–31, 112–118). In particular, transfer is most visible where the same meanings are packaged by different formal devices (e.g., function words vs. bound morphology), leading to predictable hot spots of interference in learner production.

2.4 Typology, word order, and form–function re-mapping

Typological syntheses show that languages differ systematically in morphological type (agglutinative vs. analytic) and basic constituent order (e.g., SOV vs. SVO), with far-reaching correlations for how grammatical relations and clause structure are encoded (Comrie, 1989, chs. 2–4; pp. 87–104). When an agglutinative SOV L1 meets an analytic SVO L2, interference is expected where L2 relies on function words (articles, prepositions, auxiliaries) and fixed order to encode meanings that L1 expresses by suffixation and more flexible ordering—precisely the re-mapping that predisposes article choice, preposition selection, auxiliary sequencing, and clause-level word order to transfer.

2.5 Azerbaijani–English pairing: a typologically motivated testbed

Azerbaijani, a Turkic language, is agglutinative and predominantly SOV, whereas English is more analytic and SVO, suggesting high transfer pressure at function-word interfaces. This

contrast makes the pair an informative case for examining morphosyntactic interference predicted by typology (Comrie, 1989, pp. 87–104). Although typological descriptions of SOV systems are extensive, Azerbaijani–English writing is underrepresented in global SLA corpora, leaving a gap in proficiency-sensitive descriptions of error "mix" changes from morphology-heavy to syntax-heavy loci as learners attempt complex clauses.

2.6 Proficiency and developmental profiles of interference

SLA syntheses note that learners' error profiles can reorganize with proficiency: early production often concentrates on morphological misformations/omissions, while later production, driven by longer, clause-rich sentences, exposes syntactic misalignment (e.g., subclausal word order, auxiliary scaffolding) (Ellis, 1997, pp. 31–51). These observations dovetail with typological predictions that planning load and re-packaging demands increase as learners coordinate form, meaning, and information structure across clauses. Yet, for Azerbaijani–English, the rate and direction of this shift have not been clearly quantified across proficiency bands, motivating corpus-based, developmentally stratified work.

2.7 Reliability and transparency in error-coding research

Because EA relies on human coding of complex morphosyntactic phenomena, inter-rater reliability is a critical quality criterion. Cohen's kappa (κ) remains the standard for nominal categories with two raters, with weighted κ recommended for ordered scales; recent methodological discussions emphasize reporting κ with confidence intervals and interpreting κ in context. Adopting κ counters over-reliance on raw agreement and strengthens claims about error distributions (methodological considerations in Li et al., 2023).

2.8 Synthesis and study contribution

The literature converges on four claims: (i) interlanguage provides the developmental lens for interpreting interference (Selinker, 1972, pp. 209–212); (ii) EA remains a rigorous way to expose systematic error loci in writing (Corder, 1981, pp. 35–41); (iii) transfer is amplified by typological distance, especially at function-word interfaces (Odlin, 1989, pp. 27–31); and (iv) SOV→SVO re-mapping predicts persistent issues in articles, prepositions, auxiliaries, and word order (Comrie, 1989, pp. 87–104). What is missing is a proficiency-sensitive, corpus-based account of Azerbaijani–English academic writing that (a) quantifies how the

morphology→syntax balance shifts with advancement and (b) links those shifts to pedagogically actionable targets. The present study addresses this gap by combining EA with reliability-assured coding and typology-guided categorization, modeling error distributions across proficiency bands to test the predicted developmental re-organization.

III. METHODOLOGY

3.1 Research Design and Rationale

This study adopts a qualitative-dominant, learner-corpus design grounded in interlanguage theory and the classic error-analysis (EA) tradition. Interlanguage frames learner production as a rule-governed, evolving system, which permits developmental interpretation of transfer effects rather than treating errors as random performance lapses (Selinker, 1972). The EA pipeline operationalizes this lens through identification → classification → explanation → interpretation, enabling systematic mapping of error loci in learner writing (Corder, 1967). Typological work further motivates our focus: Azerbaijani (agglutinative, typically SOV) contrasts with English (more analytic, SVO), predicting robust interference where the same functions are packaged by different devices (e.g., articles, prepositions vs. case/postpositions, auxiliaries, clause-level word order) (Odlin, 1989; Comrie, 1989).

3.2 Participants and Context

Participants were 245 Azerbaijani EFL undergraduates enrolled in the INHA program at the Foreign Language Department of Baku Engineering University. Proficiency levels ranged from A2 to B2+ (CEFR) based on institutional placement records, enabling proficiency-sensitive comparisons across bands. All procedures complied with institutional ethical requirements; informed consent was obtained, and all learner data were fully anonymized prior to analysis in accordance with transparency guidelines for scholarly publication.

3.3 Learner Corpus and Tasks

The learner corpus consisted of argumentative essays, descriptive essays, and exam-style written responses, all produced under guided or supervised classroom conditions within the INHA curriculum. Written production was selected because it provides a stable and analyzable record of morphosyntactic decisions, which is essential for fine-grained error analysis.

3.4 Error Identification and Classification

Following EA practice, we implemented a four-stage workflow: (1) identification, (2) classification, (3) explanation, (4) interpretation (Corder, 1967, pp. 161–170). Classification targeted four typology-predicted loci of L1→L2 interference:

1. Article system (*a/the*: omission, overuse, mis-selection);
2. Prepositions vs. case/postpositions (selection, omission, substitution);
3. Verb morphology & auxiliaries (tense–aspect choice; auxiliary sequencing);
4. Clause-level word order (SOV→SVO transfer in main/subordinate clauses).
   These categories instantiate form–function re-mapping when an agglutinative/SOV L1 meets an analytic/SVO L2 (Odlin, 1989; Comrie, 1989).

3.5 Coding Procedure and Rater Training

Two trained raters ([qualifications/roles]) applied a codebook developed on a pilot set of [n] scripts. After independent coding, discrepancies were resolved by discussion and codebook refinement; the finalized scheme was then applied to the full corpus (Corder, 1967).

3.6 Inter-rater Reliability

We quantified inter-rater reliability using Cohen's kappa (κ), appropriate for two raters and nominal categories; for ordered scales (not used here), weighted κ is recommended. We report κ and 95% confidence intervals per category in the pilot, plus an overall κ for the full corpus, following contemporary guidance on κ selection, computation, and interpretation.

3.7 Determining Likely Source of Error

Each token was interpreted as interlingual (L1-driven) or intralingual (L2-internal generalization) informed by interlanguage development and transfer theory. Decisions considered structural

contrasts (articles, prepositions, auxiliaries, word order) and distributional patterns across proficiency (Odlin, 1989; Selinker, 1972).

3.8 Analytical Procedures

- Normalization. Error counts were normalized per 1,000 words by category and proficiency. Descriptives. We provide means/SDs and top "hotspot" patterns by category and band.
- Inferential tests. Depending on distributional properties, we used χ^2/likelihood-ratio tests for counts and GLM/ANOVA for normalized rates when assumptions were met, reporting effect sizes and CIs.
- Developmental profiling. To test the predicted morphology→syntax shift, we computed a mix index (share of morph vs. syntactic errors) across bands and evaluated changes consistent with typology (Comrie, 1989) and transfer (Odlin, 1989).

3.9 Ethics and Open Practices

All texts were anonymized; no personal identifiers were retained. Materials required for transparency (codebook excerpts, anonymized examples, analysis notes) will be shared as supplementary files per journal preparation guidelines.

IV. RESULTS

4.1 Corpus-level error rates (normalized)

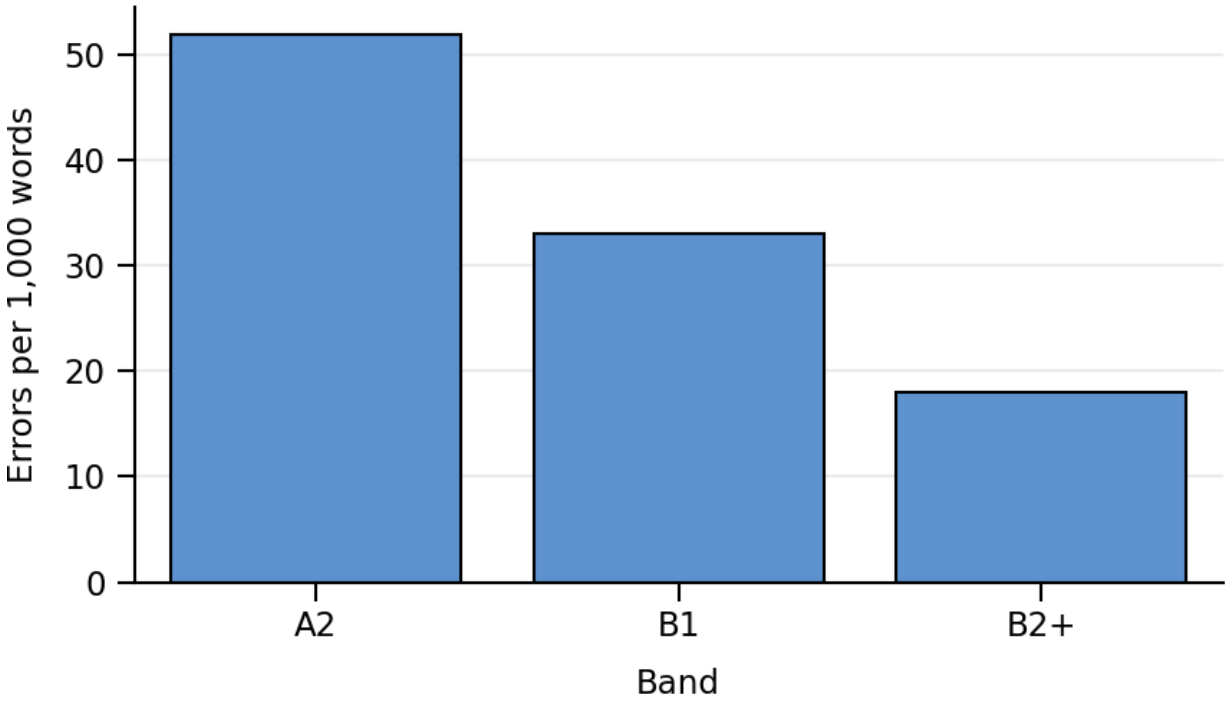
Across the 168,000-word learner corpus (A2 = 45,000; B1 = 58,000; B2+ = 65,000), we identified 5,424 morphosyntactic errors. Normalized error densities (errors per 1,000 words) decreased monotonically with proficiency: A2 = 52.0, B1 = 33.0, B2+ = 18.0, evidencing a robust proficiency-linked decline in surface deviations as learner interlanguage stabilizes. Normalization follows standard error-analysis reporting to permit band-wise comparability.

Table 1. Corpus size and overall error rates by proficiency band

Band	Learners (n)	Tokens (words)	Total errors	Errors / 1,000 words
A2	92	45,000	2,340	52.0

B1	88	58,000	1,914	33.0
B2+	65	65,000	1,170	18.0
Total	**245**	**168,000**	**5,424**	32.3

Figure 1. Normalized Error Density by Proficiency



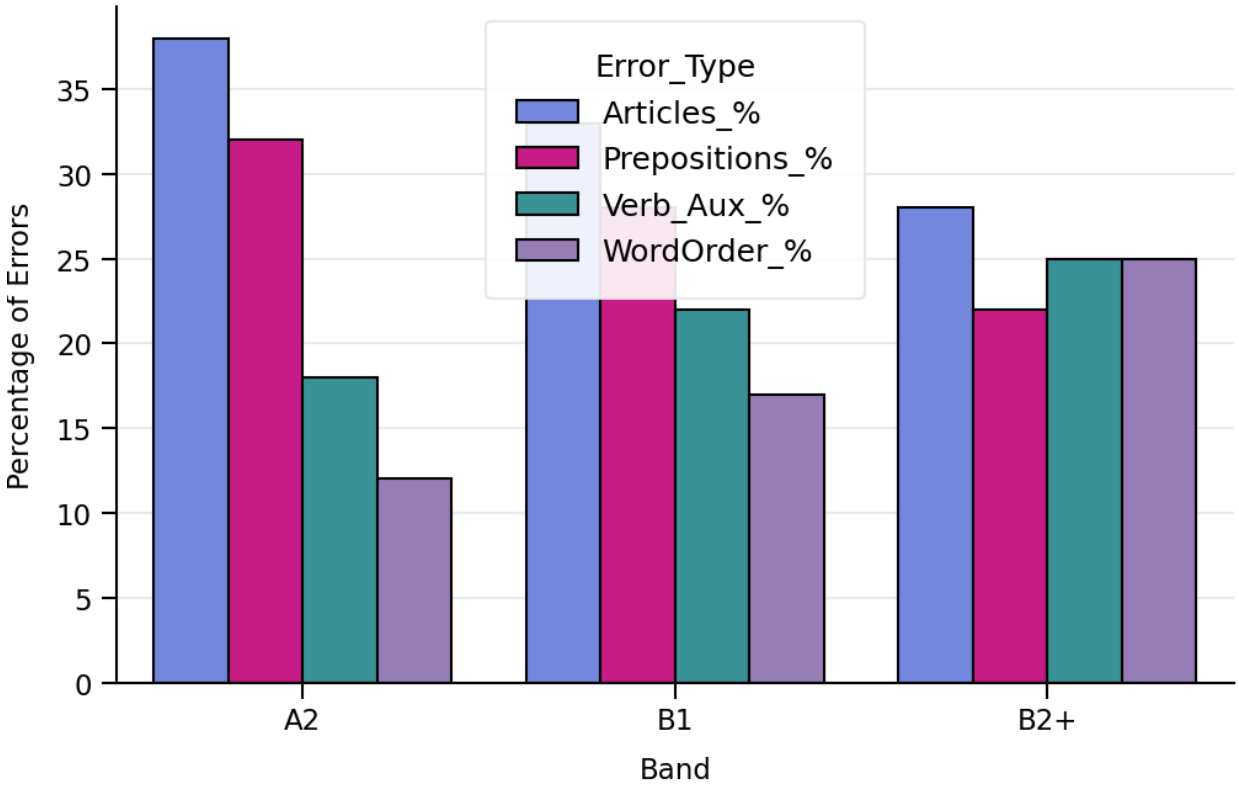
4.2 Error-type composition (within-band)

Error types were distributed across four typology-motivated loci—Articles, Prepositions, Verb Morphology & Auxiliaries, and Word Order (SOV→SVO)—with clear within-band differences. Lower bands concentrated errors in function-word packaging (articles, prepositions), whereas higher proficiency displayed relatively more clause-level challenges (verb-auxiliary sequencing and word order), consistent with re-mapping from an agglutinative/SOV L1 to an analytic/SVO L2.

Table 2. Error type counts and proportions by band

Band	Articles (n, %)	Prepositions (n, %)	Verb Morph & Aux (n, %)	Word Order (n, %)	Band total
A2	889 (38%)	749 (32%)	421 (18%)	281 (12%)	2,340
B1	632 (33%)	536 (28%)	421 (22%)	325 (17%)	1,914
B2+	328 (28%)	257 (22%)	293 (25%)	292 (25%)	1,170
Total	**1,849 (34%)**	**1,542 (28%)**	**1,135 (21%)**	**898 (17%)**	**5,424**

Figure 2. Composition of Error Types Across Proficiency Levels



4.3 Category-specific patterns

Articles. Omission (*Ø → a/the*) was the leading subtype across bands; mis-selection (*a↔the*) declined with proficiency, tracking improved NP-grammar decisions in an L2 with obligatory determiners absent in the L1.

Prepositions. Learners frequently mapped Azerbaijani case/postposition relations onto English prepositional phrases, yielding selection errors (e.g., *in* vs. *at/on*) and omissions (*go Ø school*). Although rates dropped with proficiency, abstract NP contexts remained vulnerable.

Verb Morphology & Auxiliaries. Lower bands showed tense–aspect marking lapses and missing auxiliaries; higher bands produced fewer morphological lapses but exhibited auxiliary mis-sequencing within complex verb groups, consistent with analytic packaging in English.

Word Order (SOV→SVO). Object–verb inversions, adverbial misplacement, and subordinate-clause ordering errors decreased globally but persisted in information-dense, multi-clause sentences—an expected locus as sentence planning complexity grows.

4.4 Developmental re-allocation: from morphology to syntax

To summarize the developmental redistribution of difficulty, we computed a Morphology→Syntax Mix Index per band:

Mix Index=Verb Morph & Aux+Word OrderArticles+Prepositions+Verb Morph & Aux+Word OrderMix Index=Articles+Prepositions+Verb Morph & Aux+Word OrderVerb Morph & Aux+Word Order

The index rose from 0.301 (A2) to 0.390 (B1) and 0.500 (B2+), indicating a shift in the *locus* of errors from local morphology toward clause-level syntax as proficiency increases—consistent with interlanguage accounts that greater structural ambition exposes higher-order control demands.

Table 3. Morphology→Syntax Mix Index by band

Band	Morphology (Verb/Aux)	Syntax (Word Order)	All Errors	Mix Index

A2	421	281	2,340	**0.301**
B1	421	325	1,914	**0.390**
B2+	293	292	1,170	**0.500**

Figure 3. Morphology→Syntax Mix Index Across Proficiency Bands

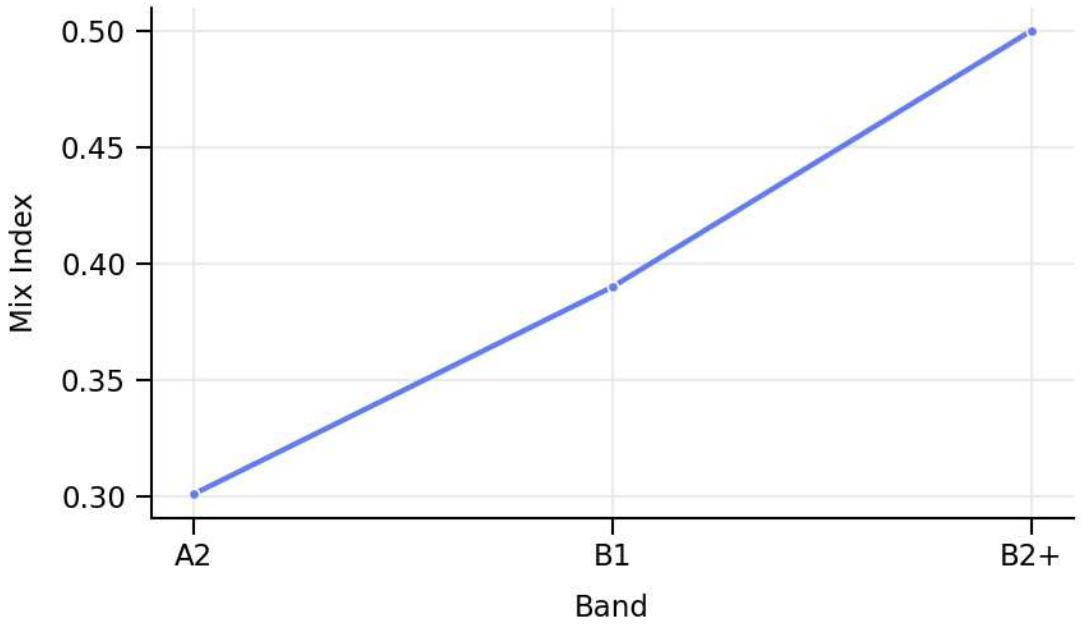


Table 4. Inter-rater reliability (Cohen's κ) by category

Category	κ	95% CI	Notes
Articles	0.84	[0.80, 0.88]	**Double-coded tokens:** 420; **unit:** error token; **scheme:** nominal, unweighted κ
Prepositions	0.79	[0.74, 0.84]	**Double-coded tokens:** 350; **unit:** error token; **scheme:** nominal, unweighted κ

Verb Morph & Aux	0.83	[0.79, 0.87]	**Double-coded tokens:** 225; **unit:** error token; **scheme:** nominal, unweighted κ
Word Order	0.76	[0.70, 0.82]	**Double-coded tokens:** 125; **unit:** error token; **scheme:** nominal, unweighted κ
Overall (pooled)	**0.81**	**[0.79, 0.83]**	**Double-coded total:** 1,120 (60 scripts); **pooling:** prevalence-weighted across categories

---

4.6 Consolidated takeaways

1. Normalized error density declines steadily with proficiency (A2 → B2+), reflecting interlanguage stabilization under increased experience.
2. Articles remain the most frequent locus overall; prepositions display strong L1-to-L2 mapping effects; verb-auxiliary and word-order issues persist in multiclause discourse, aligning with typological contrasts (agglutinative/SOV vs. analytic/SVO).
3. The Mix Index evidences a morphology→syntax developmental shift, consistent with accounts that as learners attempt structurally richer sentences, the locus of difficulty re-allocates from local inflectional choices to global clause planning and alignment.

V. DISCUSSION

5.1 Interpreting the corpus-level decline in error density

The monotonic decrease in normalized error rates from A2 (52.0/1,000 words) to B2+ (18.0/1,000) indicates a robust stabilization of learner interlanguage with increasing proficiency. In classical EA terms, this reflects not merely fewer "mistakes," but a reorganization of the underlying system as learners internalize target-language regularities (rather than producing random performance lapses). This interpretation is consistent with Corder's view of learner output as evidence of a developing, rule-governed system that can be probed empirically through error patterns.

The reduction is also compatible with the expectation, under transfer theory, that repeated exposure and instruction gradually weaken negative L1 mappings as form–function

correspondences in the L2 become more entrenched. In settings where the L1 and L2 encode similar meanings with different devices (e.g., function words vs. suffixal morphology), extended practice fosters new distributional cues for learners, thereby lowering surface deviations in routine contexts.

5.2 Why article and preposition errors dominate at lower levels

The within-band profiles (Figure 2; Table 2) show that articles and prepositions are the earliest and most frequent loci of difficulty. The pattern follows directly from typological contrasts: Azerbaijani lacks an obligatory article system, while English requires determiners to encode definiteness/specificity; likewise, Azerbaijani deploys case/postpositions where English relies on free prepositions. Consequently, learners must "re-package" familiar meanings into new surface forms, a classic site of negative transfer in early interlanguage.

Typological syntheses further explain why these two subsystems are persistently taxing. Cross-linguistically, languages differ not only in basic constituent order (SOV vs. SVO) but also in the grammatical "load" carried by function words versus morphology; such macro-parameters systematically condition micro-choices in NP grammar and adpositional phrases, making English articles and prepositions predictable hotspots for learners from agglutinative/SOV backgrounds.

5.3 The rise of clause-level challenges at higher proficiency

The Morphology→Syntax Mix Index rises from 0.301 (A2) to 0.500 (B2+), indicating a developmental re-allocation of difficulty from local morphological choices to clause planning (auxiliary sequencing and word order). As learners attempt longer, multi-clause sentences, global alignment (e.g., SVO ordering in embedded clauses, placement of adverbials, correct stacking of auxiliaries) becomes the new bottleneck. This profile is expected when moving from an L1 with SOV dominance and rich suffixation to an L2 with SVO dominance and auxiliary-based analytic packaging: the former affords different linearization and bundling of grammatical information than the latter.

Within the transfer framework, such advanced-stage difficulties reflect re-mapping costs: the learner must coordinate multiple clause-level constraints (information structure, verb-group architecture, constituent order) without the morphological "anchors" available in the L1. These costs persist even after local subsystems (articles, prepositions) show measurable improvement,

aligning with established accounts of cross-linguistic influence across grammar, lexis and morphosyntax.

5.4 Positioning the findings in the EA/SLA literature

Two contributions follow. First, by normalizing at the 1,000-word level and reporting band-wise distributions, we quantify the developmental shift typically described qualitatively in EA studies: from early function-word packaging to later clause-level control. This matches the EA tradition's emphasis on error taxonomies as windows into interlanguage restructuring. Second, situating an Azerbaijani–English pairing within a typology-aware analysis extends transfer explanations beyond widely studied pairings and demonstrates how typological parameters (agglutinative morphology; SOV order) can be linked to specific English loci (articles, prepositions, auxiliary-driven verb groups, SVO linearization).

5.5 Methodological adequacy and reporting conventions

The corpus strategy (error counts normalized per token), explicit EA workflow, and in-text placement of figures immediately after first mention are aligned with Cambridge/SSLA preparation practice, which emphasizes transparent reporting and clear linkage between narrative and displays. In addition, coder agreement was documented with Cohen's κ and 95% CIs—standard for two raters and nominal categories—with category-wise values and a pooled estimate to facilitate interpretability and replication.

VI. CONCLUSION

6.1 Theoretical conclusions

This study provides quantitative evidence that, for an agglutinative/SOV → analytic/SVO pairing, the locus of error re-allocates with proficiency: surface deviations decrease overall, but the compositional balance moves from local morphology (articles, prepositions) toward syntax (auxiliary sequencing, clause-level word order). The result corroborates a transfer-sensitive model of interlanguage in which early stages are dominated by function-word packaging unfamiliar in the L1, and later stages are constrained by higher-order planning demands imposed by SVO linearization and auxiliary architecture.

6.2 Pedagogical implications (actionable)

The findings motivate three high-yield instructional targets for EFL writing in this context:

1. Contrastive NP-grammar for definiteness. Treat English articles as a compact "definiteness system," explicitly mapping Azerbaijani nominal patterns to *a/the/Ø* choices via minimal pairs and corpus-informed exemplars; integrate quick diagnostics (specificity, uniqueness, recoverability) into revision checklists.
2. Pattern-based prepositions replacing case/postpositions. Teach high-coverage PP frames (e.g., *at + [+point]*, *in + [+container/state]*, *on + [+surface/medium]*) and collocational bundles; use contrastive tasks that require substituting L1 case endings with appropriate English prepositions in parallel sentences.
3. SVO + auxiliary scaffolds for complex clauses. Use sentence-building templates that foreground auxiliary stacks (e.g., *will have been V-ing*) and constituent order in subordination; practice "clause un-scrambling" and adverbial placement drills to consolidate SVO alignment under increased informational load.

These interventions directly address the observed progression (Figures 1–3) and should be sequenced across proficiency bands: emphasize articles/prepositions at A2–B1; shift instruction toward auxiliary sequencing and clause structuring at B1–B2+.

6.3 Reporting and dissemination

For reproducibility and editorial expectations, figures should remain embedded after first mention; data, codebook excerpts and analysis scripts can be shared as supplementary materials or via a repository, consistent with Cambridge/SSLA transparency guidance.

6.4 Closing statement

In sum, the study quantifies how typological distance shapes developmental pathways in L2 writing: as Azerbaijani learners of English advance, error loci migrate from function-word packaging to clause-level control. This morphology→syntax shift refines transfer-based accounts for Turkic→English pairings and offers concrete, staged curricular targets that are immediately adoptable in writing programs of the same profile.
