Supplementary Figure S1. Western blot images of protein expression in this study.

After protein transfer, the PVDF membrane was cut into separate strips according to molecular weight markers prior to antibody incubation, allowing simultaneous detection of proteins of different molecular weights. Therefore, a single image of the intact membrane prior to cutting is not available. The first image of each target protein was used in the main figures. Note: The sixth image for Lamin B and β -actin is not available in the original data set.
