

Figure S3. Schematic of strategy for dissecting DEGs into eight subcategories.

‘LI-DEGs’ and ‘IO-DEGs’ are intersected. A gene is determined to be ‘progressive-up’, when the gene that is upregulated both in ‘LI-DEGs’ and ‘IO-DEGs’. A gene is defined as ‘progressive-down’ when the gene is downregulated both in ‘LI-DEGs’ and ‘IO-DEGs’. A gene is ‘initial-up’, when the gene is upregulated in ‘LI-DEGs’ but is not in ‘IO-DEGs’. A gene is ‘initial-down’ when the gene is downregulated in ‘LI-DEGs’ but not in ‘IO-DEGs’. A gene is ‘later-up’ when the gene is not upregulated in ‘LI-DEGs’ but is upregulated in ‘IO-DEGs’. A gene is ‘later-down’ when the gene is not downregulated in ‘LI-DEGs’ but is downregulated in ‘IO-DEGs’. A gene is ‘up-to-down’ when the gene is upregulated in LI-DEGs and downregulated in IO-DEGs and ‘down-to-up’ when the reverse applies.
