5 (e) EDS mapping image of Sn, Mo and O elements. (f) Cycling performance of  
6 MoO<sub>3</sub>-SnO<sub>2</sub> electrodes.

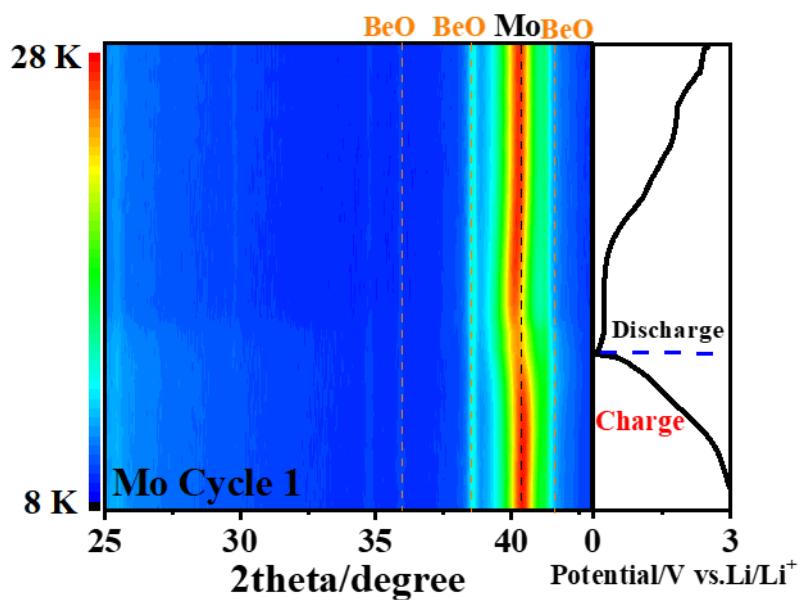

8 The HRTEM and SAED images for MoO<sub>3</sub> layer demonstrate the polycrystalline  
9 state of MoO<sub>3</sub> (Figure S11b, c). From the locally magnified HRTEM image at the  
10 interface between MoO<sub>3</sub> and SnO<sub>2</sub> layer (Figure S11d), obvious lattice fringes for MoO<sub>3</sub>  
11 and SnO<sub>2</sub> can be observed, indicating high crystallinity, which is significantly different  
12 from the amorphous interfaces in the MSM. Figure S11f displays the cycling  
13 performance of MoO<sub>3</sub>/SnO<sub>2</sub>/MoO<sub>3</sub> and MoO<sub>3</sub>/SnO<sub>2</sub>/MoO<sub>3</sub>/SnO<sub>2</sub>/MoO<sub>3</sub> electrodes.

14 After 50 cycles, the MoO<sub>3</sub>/SnO<sub>2</sub>/MoO<sub>3</sub> achieves a charge capacity retention of 61.4 %,  
15 much lower than that of the MSM. Furthermore, the charge capacity retention further

1 decreased to 49.5 % for the  $\text{MoO}_3/\text{SnO}_2/\text{MoO}_3/\text{SnO}_2/\text{MoO}_3$  with greater interfacial  
2 density, showing the negative effects of the interface in the  $\text{MoO}_3$ - $\text{SnO}_2$  electrodes.

3

6

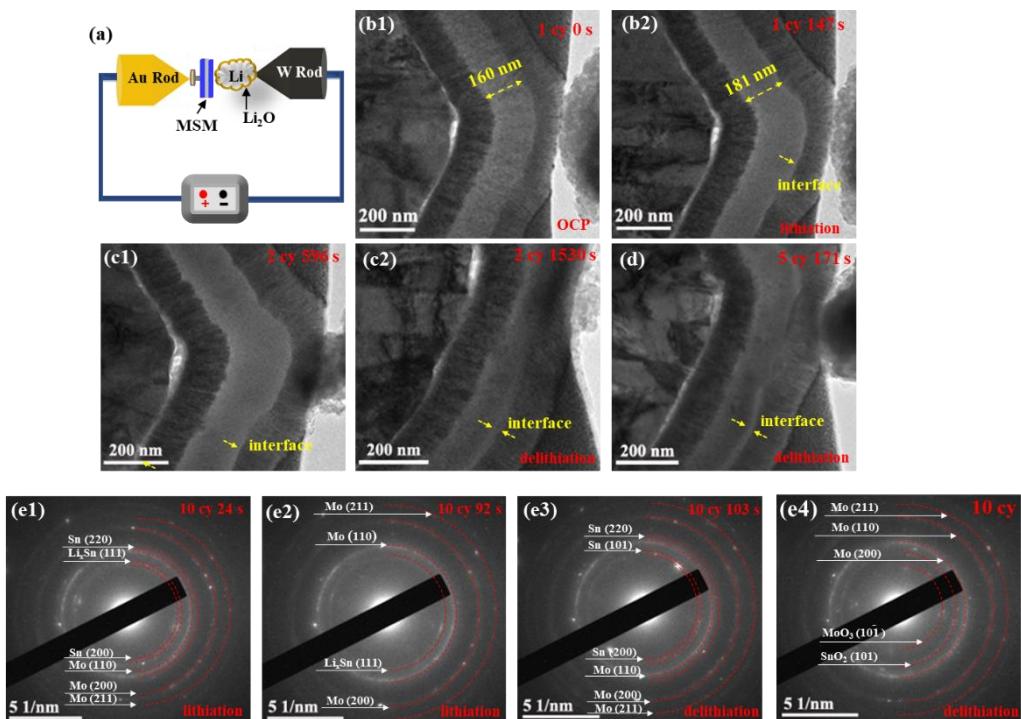

7  
8 **Figure S13.** In-situ XRD phase evolution of Mo during lithiation/delithiation

1 processes.

2 For the pure Mo film shown in Figure S13, no additional phases or impurities are  
3 presented throughout the initial cycle due to the inactivity of Mo to  $\text{Li}^+$ . However, the  
4 diffraction peak of Mo slightly weakens and shifts to the lower  $2\theta$  values when  
5 discharging to low potential, while increases and shifts to the higher  $2\theta$  values again  
6 when charging. The variation of the Mo diffraction peak reflects the existence of  
7 interaction between Mo layers and the electrolyte due to that Mo allows the solid  
8 electrolyte interface (SEI) to form directly on its surface.<sup>1</sup>

9

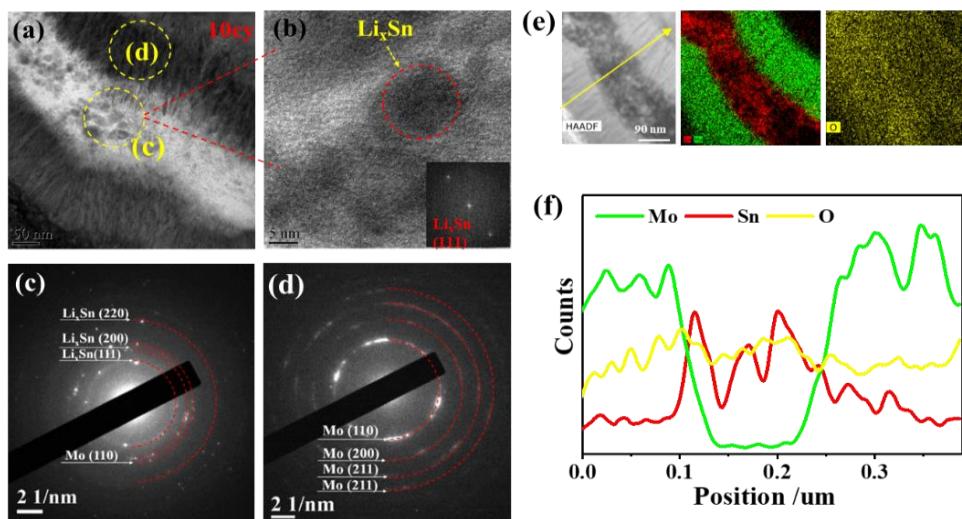

10 **Figure S14.** In-situ TEM observation of morphology and phase evolution of MSM  
11 electrode during lithiation/delithiation process. (a) Schematic illustration of in situ TEM  
12 measurement. (b-d) Sequential images of  $\text{Li}^+$  insertion/extraction in the 1st cycle (b),  
13 2nd cycle (c), 5th cycle (d). (e) In situ SAED images operated at various states during  
14 the 10th cycle.

1  
2 As illustrated in Figure S14a, the metallic Li@Li<sub>2</sub>O and the MSM film are fixed  
3 on the W and Au tips, acting as the counter electrode and working electrode,  
4 respectively. During the 1st lithiation process, slight thickness increase about 13 % of  
5 SnO<sub>2</sub> layer is observed (Figure S14b1, b2), indicating the occurrence of rapid Li<sup>+</sup>  
6 insertion (Video S1). Compared with the previous reported results of fully lithiated  
7 SnO<sub>2</sub> with 370 % volume expansion,<sup>2, 3</sup> the minor volume variation confirms that the  
8 volume effect can be effectively prevented in the MSM. After the 1st full delithiation  
9 (Figure 6f), the thickness of SnO<sub>2</sub> layer demonstrates a volume shrinkage. Furthermore,  
10 during the following several rapid lithiation/delithiation processes (Figure S14c, d and  
11 Figure 6g), the MSM remains high structure integrity guaranteed by the protection of  
12 Mo layers and the coordination effect of the amorphous interfaces composed of mixed  
13 metal oxides with stabilization effect,<sup>4</sup> which is completely different from the pure SnO<sub>2</sub>  
14 electrode (Video S2)

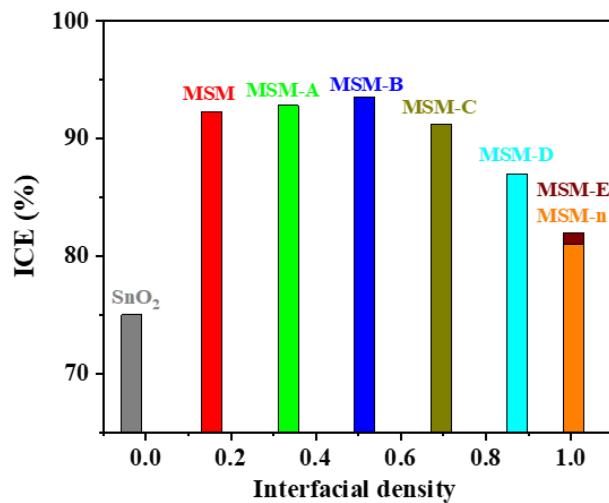

15 The interfacial effect on the reversibility of electrochemical reactions was also  
16 investigated through the in-situ SAED patterns during the 10th cycle, and the  
17 demonstrated phase evolution is consistent with the in-situ XRD results. Figure S14e  
18 and Video S1 display the in-situ SAED patterns during the 10th cycle. In the early  
19 process of lithiation (Figure S14e1), the diffraction pattern is mainly composed of Mo,  
20 Sn, accompanied by a small amount of Li<sub>x</sub>Sn, corresponding to the conversion reaction  
21 of SnO<sub>2</sub>. Then, the disappearance of Sn and the increase of Li<sub>x</sub>Sn reveal the occurrence  
22 of an alloying reaction (Figure S14e2). In the delithiation process, the dealloying

1 reaction first happens with the diffraction rings of Sn (Figure S14e3), In the fully  
 2 delithiated status (Figure S14e4), the disappearance of Sn phase again indicates the  
 3 completion of reversed conversion reaction. Furthermore, the emergence of metal  
 4 oxides ( $\text{SnO}_2$ ,  $\text{MoO}_3$ ) demonstrates superior reaction reversibility as the cycle  
 5 proceeds.<sup>5</sup> These also clearly confirm that  $\text{SnO}_2$  is the dominant reactant in these  $\text{SnO}_2$ -  
 6 Mo multilayers.

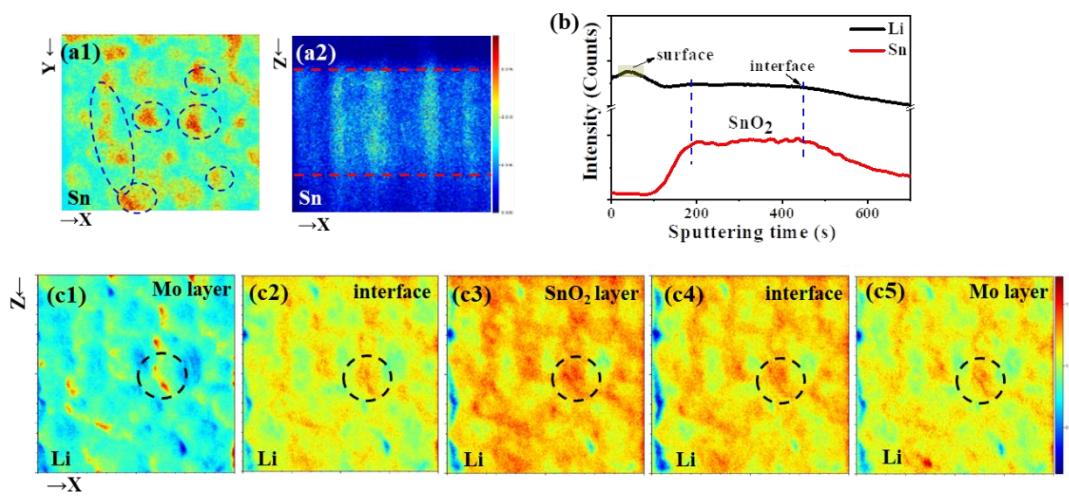

8 **Figure S15.** In-situ TEM observation of morphology and phase evolution of MSM  
 9 electrode at the fully lithiated status in the 10th cycle. (a) Typical cross-sectional  
 10 morphology. (b) HRTEM image of the  $\text{SnO}_2$  layer. (c, d) SAED images of the  $\text{SnO}_2$  and  
 11 Mo layers as marked in (a). (e, f) HADDF image, EDS mapping and line-scan images.  
 12  
 13 Figure S15 shows in-situ TEM observation for the MSM electrode at the fully  
 14 lithiated state after 10 cycles. Obviously, the  $\text{Li}_x\text{Sn}$  particles with a size of 5-10 nm have  
 15 been generated (Figures S15a-d). More apparent interdiffusion between  $\text{SnO}_2$  and Mo  
 16 layers happens as the cycles increase, and O tends to concentrate at the interfaces

1 (Figure S15e, f). As a result, the interfaces tend to capture more  $\text{Li}^+$  during discharge  
 2 and contribute more additional capacity to the multilayers electrodes. More importantly,  
 3 the concentration of O at the  $\text{SnO}_2/\text{Mo}$  interfaces would induce an increase of oxygen  
 4 vacancy in the  $\text{SnO}_2$  layer, which promotes the reversibility of conversion reactions in  
 5 lithiated  $\text{SnO}_2$ .<sup>2</sup>

6  
 7 **Figure S16.** Comparison of the ICEs for  $\text{SnO}_2$ , MSM, MSM-A, MSM-B, MSM-C,  
 8 MSM-D, MSM-E and MSM-n electrodes.

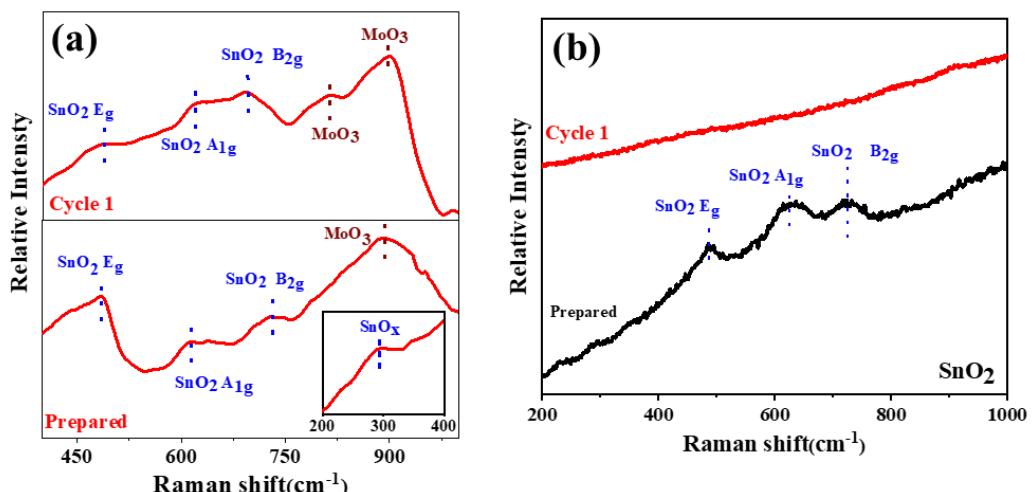

9

1 **Figure S17.** TOF-SIMS for MSM electrode as discharged to 0.01V in 1st cycle after  
2 the scavenging process, showing the distribution of Li. (a) Li distributed along the XY  
3 plane (a1) and XZ plane (a2). (b) Depth profiles of Li. (c) Distribution of Li with  
4 increasing depth along the XY plane. The depth positions are taken from (b).

5

6 In the fully lithiated state (discharged to 0.01V), after a scavenging process, as  
7 displayed in Figure S17a, b, Sn is mainly distributed in the middle layer and slightly  
8 diffuses to the Mo layers. The content of Li in MSM electrode as discharged to 0.01V  
9 in 1st cycle, as displayed in Figure S17b, c, in  $\text{SnO}_2$  layer is the highest, followed by  
10 the interfaces, and the Mo layer is the lowest. It should be mentioned that the  
11 exceptionally high Li content on the surface results from the SEI and is not discussed  
12 further.

13

14

15 **Figure S18.** SERS spectra of  $\text{SnO}_2$  electrode before and after the 1st cycle.

16 As displayed in Figure S18a, the pristine MSM shows three obvious bands for the  
17  $\text{SnO}_2$  phase at Raman shift around 480, 630, 720  $\text{cm}^{-1}$ , corresponding to the  $E_g$

1 (translational),  $A_{1g}$  (symmetric Sn-O stretching), and  $B_{2g}$  (asymmetric Sn-O stretching)  
 2 vibration mode, respectively.<sup>6, 7</sup> Besides, the  $SnO_x$  peak at  $290\text{ cm}^{-1}$  and  $MoO_3$  peak at  
 3  $890\text{ cm}^{-1}$  are observed, which come from the interfaces between  $SnO_2$  and Mo layer.  
 4 The SERS recorded at the end of first charge presents the same peaks of  $SnO_2$ ,  
 5 providing the strongest evidence to support that the conversion between  $Li_2O$  and  $SnO_2$   
 6 is reversible during the discharge/charge cycle of MSM. In contrast, no vibration of  
 7  $SnO_2$  can be detected in the pure  $SnO_2$  electrode after the initial cycle (Figure S18b).

8 **Table S1.** Preparation conditions and parameters of the various  $SnO_2$ -Mo multilayers.

Film		Time (min)	Power	Pressur
