Supplementary Figure 4. Posterior distribution of female fertility parameters. Based on 200,000 samples of the prior distribution (each simulated 10 times), filtered to 200 posterior points selected as particles in the lowest 25.3% quantile from all the distance measures described below except d6, which proved unreliable because the cage variability in egg number cannot be replicated by the model. The prior distribution is uniform across the ranges shown in each plot.
