

Supplementary Fig. S2. Effect of toothpick sampling on makomotake production

The number of makomotake per plant, total makomotake weight per plant, and weight per makomotake were compared between samples with (blue bar) or without (orange bar) toothpick sampling. The plants examined for this survey were the same as those shown in Supplementary Fig. S1. The values are the means $\pm$ SE of three biological replicates. There were no statistically significant differences in the means between the two experimental groups as a result of Welch's *t*-test.
