1. General Experimental Section

All manipulations were carried out using standard Schlenk-line and glovebox techniques under an inert atmosphere. An MBraun Labmaster glovebox with an atmosphere of N2 was employed, operating at < 0.1 ppm O₂ and < 0.1 ppm H₂O. Glassware was dried for at least 12 h at 125 °C prior to use. Toluene and hexane were dried over activated alumina from an SPS (solvent purification system) based upon the Grubbs design, pentane was distilled over CaH2 and all solvents were stored over activated 3Å molecular sieves and degassed via the freeze-pump-thaw method prior to use. Benzene-d₆ and cyclohexane-d₆ were purchased dry and stored over activated 3Å molecular sieves. Ethene gas was purchased from CK isotopes. Dihydrogen gas was obtained from a PEAK Scientific hydrogen generator. NMR-scale reactions were conducted in J Young tap tubes and prepared in a glovebox. NMR tubes were heated using a DrySyn NMR tube heating block or a Julabo Corio CD-BC4 oil bath. Capillary internal standards of mesitylene in benzene- d_6 and cyclohexane- d_6 were used to obtain NMR yields where appropriate. ¹H (tetramethylsilane; 0 ppm) and ¹³C (tetramethylsilane; 0 ppm) NMR spectra were obtained on BRUKER 400 MHz, 700 MHz or 800 MHz (with cryoprobe) instruments; all chemical shift values are quoted in ppm. Data was processed using MestReNova software. Elemental analysis was conducted by Orfhlaith McCullough at London Metropolitan University and has been obtained to the best of our abilities given the extremely air and moisture sensitive nature of the compounds. UV spectra were acquired using an Agilent Cary100 UV-Vis spectrometer. EPR spectra were obtained using a Magnettech ESR5000 at the PEPR facility (Imperial College London). Aluminium dihydride complexes, compounds II, A, [(MesBDIMg)₂], and dipp/p-tolAmAlMe₂ were synthesised via modified literature procedures.^{1–5}

2. Synthetic procedures

Precursor synthesis

Compound 1

Aluminium dihydride complex (1 equiv.) was dissolved in hexane (20 mL) and a solution of iodine (1 equiv.) in hexane was added dropwise with stirring until suspension remained light yellow. The mixture was then stirred for a further hour, during which time the colour disappeared. The solvent was removed *in vacuo* and the solid crystallised from toluene, giving the product as a colourless crystalline solid.

Compound 5

Route 1: Potassium (1 equiv.) and $\mathbf{1}^{p\text{-tol}}$ (1 equiv.) were stirred vigorously in hexane (15 mL) for 8 days. The solvent was removed *in vacuo* and the product was extracted into toluene, then recrystallised at -30 °C. The product was isolated as a colourless crystalline solid.*

Route 2: To a J Young NMR tube charged with a solution of **1** (2 equiv.) in benzene- d_6 (0.6 mL) was added II (1 equiv.). The resultant solution was

heated to 80 °C for 3 hours and allowed to cool slowly to room temperature. The solution was decanted, affording **5** as colourless crystals suitable for single-crystal X-ray diffraction.

*The low solubility of 5^{p-tol} in hexane, toluene and benzene makes isolating the product from the finely divided KI challenging, decreasing the isolated yield.

5^{m-xyl}

Synthesis of compound 2^{p-tol} and 2^{m-xyl} (cyclotrialumanes)

2^{p-tol}

Route 1: Aluminium diiodide 1^{p-tol} (200 mg, 0.27 mmol) and potassium (42 mg, 1.1 mmol) were stirred vigorously in pentane (15 mL) for 24 hours[†], during which time the solution turned dark red-black (Figure S 2). The mixture was filtered and stored at -30 °C overnight, affording the product as a black crystalline solid (37.8 mg, 29 %).

Further crops were obtained by concentrating and cooling the filtrate to -30 °C, although these are contaminated with a mixture of $5^{p-\text{tol}}$ and A. The yield of total crude material is generally around 60%, and several small crystalline crops of

 $2^{p-\text{tol}}$ can be obtained from this in varying yields. Doing the reactions on smaller scale (100 mg) leads to higher yields, likely due to the low solubility of $5^{p-\text{tol}}$ limiting reaction efficiency on larger scale. This could be surmounted by working at higher dilution.

†As the reduction is heterogeneous, the rate of reaction depends on the efficiency of stirring and consequently reaction times can vary.⁶ Generally, the rate of reduction of $\mathbf{1}^{m-xyl}$ is faster than $\mathbf{1}^{p-tol}$ (reactions generally complete at 16 hours and 24 hours respectively from ¹H NMR of aliquots). However, the first reduction product ($\mathbf{5}^{m-xyl/p-tol}$) is essentially insoluble in the reaction solvent so it is difficult to determine when this has been fully consumed by aliquot.

Route 2: Compound **II** (4.3 mg, 0.009 mmol) and compound **A** (9.4 mg, 0.009 mmol) were combined in cyclohexane- d_{12} (0.6 mL) and heated at 80 °C for 1 hour, at which point a mixture of all four species were observed in solution (Figure S 11). The resonances of $2^{p\text{-tol}}$ match those observed when synthesised independently *via* route 1, but it does not appear possible to push the equilibrium of the reaction far enough to allow isolation of the products.

2^{m-xyl}

A vial charged with aluminium diiodide complex $\mathbf{1}^{m-xyl}$ (1 equiv.), finely divided potassium (4 equiv.) and hexane (ca. 15 mL) was vigorously stirred at room temperature for 16 hours, affording a deep red-black solution. The mixture was allowed to settle, filtered, concentrated and stored at -40 °C overnight to afford $\mathbf{2}^{m-xyl}$ as a black crystalline solid. Further crops were obtained by the same method to afford pure $\mathbf{2}^{m-xyl}$ (54 mg, 82%).

The yield of total crude material is as high as 95%, although in all cases crystalline crops were used for onward reactivity.

Note: Several aliphatic solvents have been tested for the reaction, and generally the reactions have been found to proceed similarly in pentane, hexane and cyclohexane for $\mathbf{1}^{p\text{-tol}}$, however $\mathbf{1}^{m\text{-xyl}}$ appears more sensitive to the reaction solvent, with lower yields obtained from attempted reductions in pentane, and notably larger quantities of the apparent decomposition product $[(^{\text{Dip}}Am^{m\text{Xyl}}AIH)_2]$ (dihydrodialane) (as verified *via* comparison with independently synthesised $\mathbf{8}^{m\text{-xyl}}$).

Reactivity studies with 2^{p-tol} and 2^{m-xyl}

Compound 3

Route 1: A J Young NMR tube charged with a dark red-black solution of **2** (1 equiv.) in excess benzene (0.6 mL) was heated to 80 °C for three hours. The resultant red-orange solution was dried *in vacuo* and redissolved in benzene- d_6 . ¹H NMR spectroscopic analysis showed full conversion of **2** to **3**.

Route 2: A vial containing $\mathbf{1}^{p\text{-tol}}$ (1 equiv.) and KC₈ (2 equiv.)* in benzene (15 mL) was stirred vigorously for 5 days. The solution was allowed to settle and filtered before concentrating to an oil and adding pentane, to afford the product as a red crystalline solid.

*The route 2 reaction was also attempted with K as the reducing agent, but although the starting material was consumed, very little of **3** was formed. This may be in part due to difficulties finely dividing K in benzene, which results in a reduced surface area and precludes effective reduction.

Route 1: 34.8 mg **2**^{*p*-tol}, 0.6 mL benzene, yield: 29.5 mg (78%).

Route 2: 200 mg 1^{p-tol}, 74 mg KC₈, yield 103 mg (72%).

To a J Young NMR tube charged with a solution of 2 (1 equiv.) in cyclohexane- d_{12} (0.6 mL) was added *bis*(trimethylsilyl)acetylene (3 equiv.). Synthesis of compounds 10, 11 and 12

To a J Young NMR tube charged with a frozen degassed solution of 2 (1 equiv.) in cyclohexane- d_{12} (0.6 mL) was added ethene gas (1 atm.). The frozen solution was allowed to thaw, affording a redorange solution, which over the course of approximately 10 hours lost intensity, eventually affording a colourless solution. Product distribution could be worked out via ¹H NMR spectroscopy versus a mesitylene internal standard.

For assignment of **10**^{*p*-tol} and **10**^{*m*-xyl} in both cases, due to the number of resonances and overlapping crosspeaks assignment of ¹³C resonances is tentative; unfortunately it proved impossible to completely separate **10** from **11** and **12**, nevertheless acquiring ¹H spectra on an 800 MHz spectrometer allowed for ¹H NMR assignment (Figure S 86).

Again, for assignment of $\mathbf{12}^{p\text{-tol}}$ and $\mathbf{12}^{m\text{-xyl}}$ due to the number of resonances and overlapping crosspeaks assignment of aromatic and all ¹³C resonances is not possible, but tentative assignment of ¹H resonances is possible using an 800 MHz spectrometer (Figure S 92).

4. X-ray crystallographic data

All experiments were performed at 150 K or 120 K using a Cu K α radiation source (λ = 1.54184 Å) or at 100 K using Mo $K\alpha$ (λ = 0.7107 Å) radiation. Measurements on compounds 2^{m-xyl} -1, 9^{m-xyl} and 10^{m-xyl} were made using a twin-source Agilent Oxford Diffraction SuperNova diffractometer with a microfocus Cu K α X-ray beam (50 kV, 0.8 mA) and an Atlas CCD detector. Measurements on 2^{p-tol} were performed using a twin-source Oxford Xcaliubur Gemini diffractometer with a Sapphire 3 CCD plate. The crystal structures of 1^{p-tol} , 2^{p-tol} -1, 5^{p-tol} , 5^{m-xyl} , 2^{m-xyl} , 2^{m-xyl} and 11^{m-xyl} were obtained using a Synergy-S diffractometer equipped with a Dectris Eiger2 1M detector. Cell refinement, data collection and data reduction for all experiments were performed using Rigaku CrysAlisPro. All structures were solved with ShelXT¹⁰ and ShelXL¹¹, both programs implemented within the Olex2¹² suite. All atoms, except hydrogen, had atomic coordinates and anisotropic thermal parameters refined to convergence using least-square methods on F². Only hydrogen atoms bound to carbons are present, and they were placed in geometric positions and refined with riding modes.

Single crystals of $\mathbf{2}^{p\text{-tol}}$ were grown by cooling a saturated hexane solution. $\mathbf{2}^{p\text{-tol}}$ was found to crystallise in the $P\overline{1}$ space group, with two molecules in the unit cell ($\mathbf{2}^{p\text{-tol}}$ - \mathbf{A} and $\mathbf{2}^{p\text{-tol}}$ - \mathbf{B}). A solvent mask (SQUEEZE) was applied to remove the electron density of 4 hexanes per unit cell. There was disorder across 4 diisopropyl groups, each of which were modelled across two positions.

There is residual electron density located off the Al-Al bonds in both molecules, corresponding to an average weight of 0.48 for $2^{p\text{-tol}}$ -A and 0.42 for $2^{p\text{-tol}}$ -B. This density is also seen when the solvent mask (SQUEEZE) is removed. While modelling this density as a hydride can lead to a stable refinement, the density is better explained by the electron rich Al-Al bonding interactions (see Section 5).

Single crystal X-ray data for 2^{p-tol}-1 – second polymorph

A second polymorph of 2^{p-tol} was observed when growing crystals by fractionally crystallising away from the products of route 2 in hexane (see Figure S 11). $2^{p-tol}-1$ crystallised in the $P\overline{1}$ space group, with two molecules in the unit cell. The structure contained disordered hexane, and an attempt was made to apply a solvent mask (SQUEEZE) to remove this, with two voids containing 3.6 and 3.2 molecules of hexane per unit cell. However, due to an issue with the data collection there were 11 missing reflections below Theta(min), which may affect how reliable the mask is. Therefore, the data is included for completeness but is not discussed in detail in the main manuscript.

5. Computational analysis

All DFT calculations were performed using the Gaussian 16 software (Revision C.01) as compiled on King's College London's CREATE High Performance Computing (HPC) cluster. 13,14 Initial coordinates were obtained from the relevant SC-XRD structures. All geometries were optimised without symmetry constraints at the M06-2X-D3 level of theory, including Grimme's atom-pairwise correction to account for dispersion effects. Ahlrichs' def2-TZVP basis set was used for all metal centres and donor atoms directly bound to metal centres. Def2-SVP was placed on the remaining centres (C, H). For all calculations, an ultrafine integration grid corresponding to a pruned grid of 99 radial shells and 590 angular points per shell was employed to ensure highly accurate numerical integration of the electron density. The same procedure was used for literature compounds. In all cases, ground state geometries were confirmed by way of frequency calculation at the same level of theory to indicate the absence of negative eigenvalues in the Hessian matrix. All subsequent single point corrections and analyses were performed at the SMD-M06-2X-D3/def2-TZVP level of theory, using the SMD solvation model by Truhlar, Cramer and Marenich, with solvent parameters corresponding to those of cyclohexane (ϵ =2.0165). 15

Time dependent (TD) DFT calculations were carried out at the SMD-M06-2X-D3/def2-TZVP (cyclohexane, ϵ =2.0165) level of theory, employing the Tamm-Dancoff approximation (TDA). Natural Bond Orbital analysis was conducted using the NBO program (Version 3.1).¹⁶ Quantum Theory of Atoms in Molecules (QTAIM) analysis was conducted using the AIMAII package, from the Gaussian obtained-wavefunction file.¹⁷ Isosurface mapping of the Electron Localization Function (ELF) was performed using the Multiwfn package, employing the high quality grid preset – covering the whole system, about 1,728,000 points in total.^{18,19}

Figures of all structures and isosurface plots were generated with ChemCraft (Version 1.8) and UCSF ChimeraX (Version 1.61). ^{20,21}

Given the complexity of the electronic structure, ensuring functional best fit was a priority before conducting in depth analysis. The fitting of four common functionals: B3LYP, ω B97XD, M06-L and M06-2x was tested against experimental geometry values obtained from two separate single crystal structures (four units) and UV-Vis spectroscopic parameters.

The M06-2x-D3 functional was selected for the remainder of the analysis work based on its excellent adherence to the crystallographically determined geometries and mapping of the key TD-DFT transition bands seen *via* UV-Vis spectroscopy. All other functionals failed to accurately determine reasonable transition wavelengths and resolve both experimentally observed bands.
