## 51 **1. Model Construction**

### 52 **1.1 Training and Inference Algorithms**

53 Pseudocode for the algorithms utilized in both the training and inference phases of the  
54 SE3-BiLingoMol model is provided. Ligand representation was established using the  
55 FSMILES<sup>1</sup> methodology.

56 The specific procedures for training the self-refinement module are not included within  
57 the primary model training algorithm. This is because the self-refinement module was  
58 instantiated as a replicate of the pre-trained ligand decoder, inheriting its architectural  
59 layers and corresponding parameters. Consequently, the training of this module was  
60 readily accomplished by adhering to the established model training protocol, specifically  
61 by incorporating a bidirectional attention mask, while maintaining fixed parameters for  
62 all other modules. Notably, the self-refinement module converged efficiently, requiring a  
63 substantially reduced number of epochs (e.g., 30 epochs) compared to the comprehensive  
64 training of the entire SE3-BiLingoMol model.

---

**Algorithm 1** Model Training

---

**Input:** PDB files of all binding proteins, each with a co-crystallized or docked tool ligand (reference ligand) in the pocket

**Input:** SDF files of all small-molecule ligands

**Input:** Identified non-covalent interactions(NCI) by ODDT for each complex

**Input:** Identified pocket features, e.g., hydrogen-bond donor/acceptor, hydrophobicity, aromaticity, formal charges, and residue types

// Prepare training dataset

- 1: Define pockets as all residues that are within 6 Å from its reference ligand
- 2: Define contact sites as all pocket atom sites that are within 4 Å from its reference ligand
- 3: Define pocket NCI sites as the pocket atom sites of identified NCIs
- 4: Define pocket feature sites as the pocket atom sites of identified pocket features
- 5: Obtain pocket atom tokens using element types, and additional "pad", "undefined" tokens
- 6: Obtain ligand tokens using FSMILES tokenizer

// Training

7: num\_epochs=300

8: batch\_size=30

9: **for** each epoch **do**

10:     **for** each batch **do**

11:         Generate pocket multivector embeddings  $R^{pocket}$

12:         Generate pocket residue embeddings  $E^{residue}$

13:         Generate pocket feature embeddings  $E^{feature}$

14:         Generate pocket NCI embeddings  $E^{NCIs}$

15:         Generate pocket contact embeddings  $E^{contact}$

16:          $E^{pocket} = E^{residue} + \text{Concat}(E^{feature}, E^{NCIs} + E^{contact})$

17:         Generate ligand multivector and FSMILES embeddings  $R^{lig}, E^{lig}$

18:          $Z^{pocket, MV}, Z^{pocket, S} = \text{Encoder}(R^{pocket}, E^{pocket})$

19:          $Z^{lig, MV}, Z^{lig, S} = \text{Decoder}(R^{lig}, E^{lig}, Z^{pocket, MV}, Z^{pocket, S})$

20:         ligand\_token\_logits =  $\text{MLP}_{token}(Z^{lig, MV}, Z^{lig, S})$

21:          $R_{preds}^{lig} = \text{MLP}_{coords}(Z^{lig, MV}[:, :, -1, \dots], Z^{lig, S}[:, :, -1, \dots], E^{lig}[:, 1 : \dots])$

22:         Compute ligand token loss and ligand coordinates loss

23:         Compute auxiliary loss

24:         Backpropagate the total loss and use AdamW optimizer to update model parameters

25:     **end for**

26: **end for**

---

---

**Algorithm 2** Molecule Inference

---

**Input:** PDB file of a binding pocket

**Input:** SDF file of a reference ligand only for pocket contact site featurization

**Input:** (*Optional*) SDF file of a molecular fragment

**Input:** (*Optional*) Non-covalent interaction sites of pocket atom

```
// Prepare input pocket embeddings
1: Obtain pocket multivector embeddings  $R^{pocket}$ 
2: Obtain pocket token embedding  $E^{residue}$ 
3: Obtain pocket features embedding  $E^{feature}$ 
4: Obtain pocket contact embedding  $E^{contact}$ 
5: if input interaction sites are provided then
6:   Obtain pocket interaction embedding  $E^{NCIs}$  from input
7: else
8:   Obtain  $E^{NCIs}$  by randomly selecting 4 pocket feature sites that are
   closed to the pocket center
9: end if
// Prepare input ligand embeddings
10: if input molecular fragment is provided then
11:   Obtain ligand multivector embeddings  $R^{lig}$  from fragment atomic posi-
   tions
12:   Obtain ligand token embeddings  $E^{lig}$  by FSMILES tokenization of the
   fragment
13: else
14:   Set  $E^{lig}$  to the embedding of '[START]' token
15:   Obtain  $R^{lig}$  using randomly selected contact site position embeddings
16: end if
// Start auto-regressive generation (generate one molecule as an example)
17: max_length= 100
18: temperature= 1
19:  $Z^{pocket,MV}, Z^{pocket,S} = \text{Encoder}(R^{pocket}, E^{pocket})$ 
20: while current ligand sequence length  $l < \text{max\_length}$  do
21:    $Z^{lig,MV}, Z^{lig,S} = \text{Decoder}(R^{lig}, E^{lig}, Z^{pocket,MV}, Z^{pocket,S})$ 
22:   ligand_token_logits =  $\text{MLP}_{token}(Z_l^{lig,MV}, Z_l^{lig,S})$ 
23:   ligand_token_probs =  $\text{Softmax}(\text{ligand\_token\_logits}/\text{temperature})$ 
24:   Sample a ligand token by multinomial sampling
25:   Obtain the embedding  $E_l^{lig}$  of the sampled token
26:    $R_l^{lig} = \text{MLP}_{coords}(Z_l^{lig,MV}, Z_l^{lig,S}, E_l^{lig})$ 
27:   if current token is '[END]' token then
28:     Terminate generation before reaching max_length
29:   end if
30: end while
31:  $R_{refined}^{lig} = \text{SelfRefinement}(E^{lig}, R^{lig})$ 
32: Obtain generated molecule by transforming all predicted tokens and coor-
   dinates
```

**Output:** generated molecule

---

---

**Algorithm 3** Molecular representation using fragment-SMILES

---

**Input:** A molecule SMILES with its 3D positions

**Input:** Predefined SMILES vocabulary, vocab1

**Input:** Predefined fragment-SMILES vocabulary, vocab2

```
1: Fragment the molecule into different fragments based on each single bond
   that is (1) not in a ring, (2) attached to a ring and (3) not attached to
   hydrogen atoms
2: FSMILES_list = ['start']
3: for For each fragment do
4:   Recognize and tokenize atoms, bonds, branches, rings, stereochemistry,
   charges and isotopes from SMILES using vocab1
   // Incorporate ring information into SMILES tokens
5:   Recognize ring type for each atom and set ring type '0' for atoms that
   do not form a ring and non-element tokens
6:   for For each token do
7:     Combine the SMILES token with its ring type
8:     Push the new token into FSMILES_list
9:   end for
   // Use a 'sep' token to distinguish different fragments
10:  FSMILES_list += 'sep'
11: end for
12: FSMILES_list += 'end'
13: Transform FSMILES_list into FSMILES_code using the index of each
   fragment-SMILES token in vocab2

   // Process token positions
14: Centralize all atomic positions
15: Find the parent token (defined as an element token) for each token
16: Assign non-element token position as the one of its parent token
Output: fragment-SMILES token list and position list
```

---

## 68 1.2 Optimization Techniques Used for SE3-Bilingomol Inference 69 Speedup

70 SE3-BiLingoMol functions as an SE(3)-equivariant Transformer-based language  
71 model, facilitating molecular generation via autoregressive sampling. During the  
72 inference phase, three principal optimization techniques were employed to significantly  
73 reduce computational time.

74 Firstly, a Key-Value (KV) cache was implemented. This optimization, widely  
75 adopted in many large language models, stores the key and value matrices from previous  
76 decoding steps, enabling their reuse in the current decoding step. This approach  
77 substantially reduces computational consumption by eliminating redundant key and value  
78 computations.

79 Secondly, consistent with the official implementation of the Geometric Algebra  
80 Transformer<sup>2</sup>, multi-query attention<sup>3</sup> was utilized instead of multi-head attention to  
81 mitigate memory consumption.

82 Finally, a specific optimization was applied to multi-query attention computation. In  
83 standard implementations, GPUs repeatedly load identical key and value data into shared  
84 memory for different queries, thereby increasing bandwidth demands. To address this, all  
85 queries were loaded into shared memory simultaneously during decoding steps, which  
86 consequently reduced I/O operations. Concurrently, by concatenating all queries into a  
87 single matrix, the self-attention computation was transformed from General Matrix-  
88 Vector multiplication (GEMV) to General Matrix-Matrix multiplication (GEMM). This  
89 enabled more efficient utilization of GPU tensor cores, resulting in accelerated  
90 computation.

91

## 92 1.3 Features representations using the projective geometric algebra

93

94 **Table S1. Representations of scalar features, 3D points and symmetry operations using the**  
95 **projective geometric algebra  $G(\mathbb{R}^{3,0,1})$ .** The non-zero component coefficients of the 16-  
96 dimensional multivector  $x$  are listed, and a generic multivector can be expressed as in Eq. 1.

| Geometric objects/ symmetry operations   | Multivector                            | mapping      |
|--|--|--------------|
| Scalar $s \in \mathbb{R}$  | $x_s$                                  | $= s$        |
| Point $p \in \mathbb{R}^3$   | $(x_{012}, x_{013}, x_{023}, x_{123})$ | $= (p, 1)$   |
| Translation $t \in \mathbb{R}^3$   | $(x_s, x_{01}, x_{02}, x_{03})$        | $= (1, t/2)$ |
| Rotation expressed as quaternion $q \in \mathbb{R}^4$  | $(x_s, x_{01}, x_{02}, x_{03})$        | $= q$        |
| Point reflection through $p \in \mathbb{R}^3$  | $(x_{012}, x_{013}, x_{023}, x_{123})$ | $= (p, 1)$   |
| Reflection through plane w/ normal $n \in \mathbb{R}^3$ ,<br>origin shift $d \in \mathbb{R}$ | $(x_0, x_1, x_2, x_3)$                 | $= (d, n)$   |

97

98

99

100 **1.4 Hyperparameters of SE3-BiLingoMol**101 **Supplementary Information Table S2.** Hyperparameters of SE3-BiLingoMol for model  
102 architecture, training and inference.

| Hyperparameter  | Value                     |
|---|---------------------------|
| Number of pocket encoder blocks   | 20                        |
| Number of ligand decoder blocks   | 20                        |
| Number of self-refinement blocks  | 20                        |
| Hidden size of multi-vector channels  | 64                        |
| Hidden size of scalar channels  | 128                       |
| Hidden size of scalar embeddings  | 512                       |
| Scalar channel dimensions of equivariant MLP                                | [128, 256, 128]           |
| Multi-vector channel dimensions of equivariant MLP                          | [64, 128, 64]             |
| Number of attention heads   | 8                         |
| Scalar channel dimensions of token head                                     | [128, 256, 256]           |
| Multi-vector channel dimension of token head                                | [64, 128, 64]             |
| Scalar channel dimension of coordinate head                                 | [640, 256, 128]           |

103

104

## 105 2. Model Evaluation

### 106 2.1 Definition of Evaluation Metrics

107 (i) **# Generated Molecules.** The sum of total number of generated molecules across 102  
108 targets, with an upper limit of 1000 per target.

109 (ii) **Mean MW.** The averaged molecular weight of all generated molecules.

110 (iii) **Mean QED.** The average quantitative estimate of drug-likeness of all generated  
111 molecules.

112 (iv) **Mean SAS.** The average synthetic accessibility score of all generated molecules.

113 (v) **% Druglike Molecules.** The ratio of molecules with QED > 0.3 and SAS < 5 over all  
114 generated molecules.

115 (vi) **% Non-aromatic rings.** The score estimates the average ratio of non-aromatic rings  
116 in the generated molecules. Specifically, for each molecule, the atomic masses of all atoms  
117 in non-aromatic rings (determined using RDKit) are summed, and the non-aromatic ring  
118 ratio is defined as the ratio of the atomic masses of atoms of non-aromatic rings to its total  
119 molecular weight.

120 (vii) **Diversity.** The score measures molecular diversity, where the similarity score of  
121 average pair-wise Tanimoto similarity of molecules generated for the same target was first  
122 computed, and the Diversity was defined as 1 - similarity score.

123 (viii) **% Conformation Validity.** The ratio of molecules passing high-energy atom  
124 detection (HEAD)<sup>4</sup> overall all generated molecules.

125 (ix) **Strain Energy 25%, 50%, 75%.** Strain energy (in unit kcal/mol) of the 25% quantile,  
126 medium, and 75% quantile of all predicted strain energies by PoseCheck<sup>5</sup> at a level of  
127 Universal Force Fields.

128 (x) **Mean Min-in-place Score.** The weighted average of min-in-place docking score using  
129 "mininplace" method of Schrödinger Glide module<sup>6</sup>, where the number of druglike  
130 molecules for different targets are considered as the weights. During calculation, we only  
131 considered druglike molecules with a negative min-in-place score.

132 (xi) **Mean Redocking Score.** The weighted average of redocking score using "docking"  
133 method of Schrödinger Glide module, where the number of druglike molecules for different  
134 targets are considered as the weights. During calculation, we only considered druglike  
135 molecules with a negative redocking score.

136 (xii) **% Min-in-place < Re-docking Score.** The ratio of molecules whose min-in-place  
137 docking score is lower than redocking score over all generated druglike molecules. During  
138 calculation, we only considered druglike molecules with a negative min-in-place and  
139 redocking score.

140 (xiii) **% IMP<sup>7</sup>.** The ratio of molecules whose min-in-place docking score is lower than the  
141 lowest docking score of active compounds (calculated using Schrödinger Glide module with

142 “docking” method) on that target, over all generated druglike molecules. During  
143 calculation, we only considered druglike molecules with a negative min-in-place score.

144 (xiv) **PLIF Recovery Rate**<sup>8</sup>. This metric is a measurement of the fraction of non-covalent  
145 interactions in the crystal ligand pose that are successfully replicated in the generated  
146 molecule pose using ProLIF, defined as,

147 
$$\text{PLIF Recovery} = \frac{\sum_{i,r} \min(C_{i,r}, P_{i,r})}{\sum_{i,r} C_{i,r}},$$

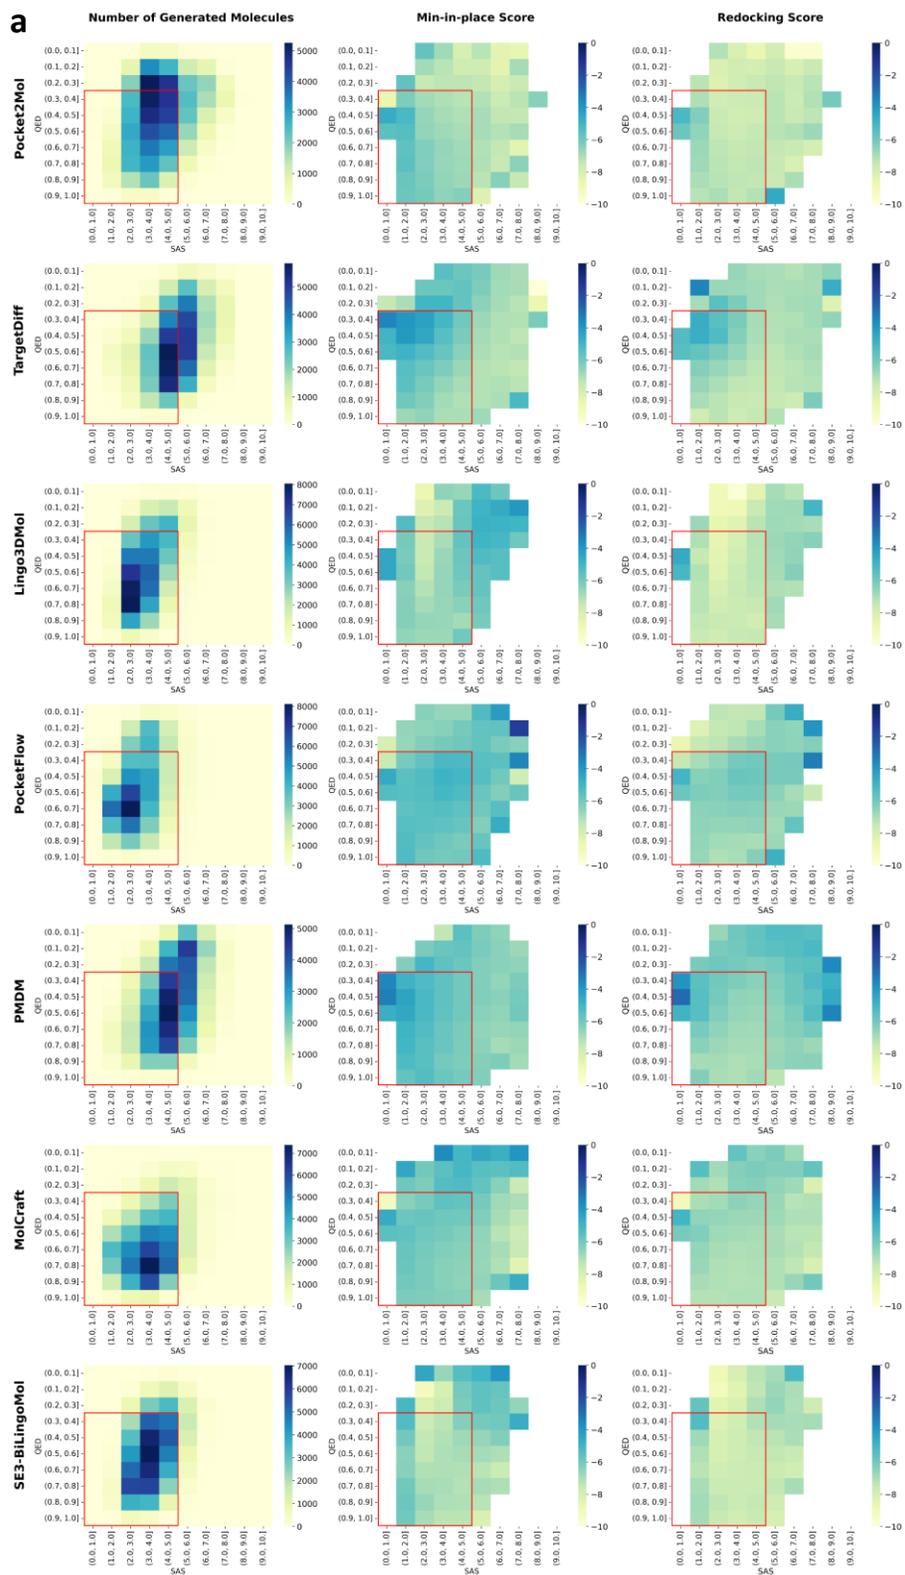

148 where  $C_{i,r}$  is the count of type- $i$  interaction that crystal ligand formed with residue  $r$ ,  
149 and  $P_{i,r}$  is the count of type- $i$  interaction that a generated molecule formed with residue  $r$ .  
150 Here, we considered interactions including hydrogen bond acceptor/donor, halogen bond  
151 acceptor/donor,  $\pi$ - $\pi$  stacking, cation- $\pi$ ,  $\pi$ -cation, anionic and cationic interactions were  
152 calculated by ProLIF.

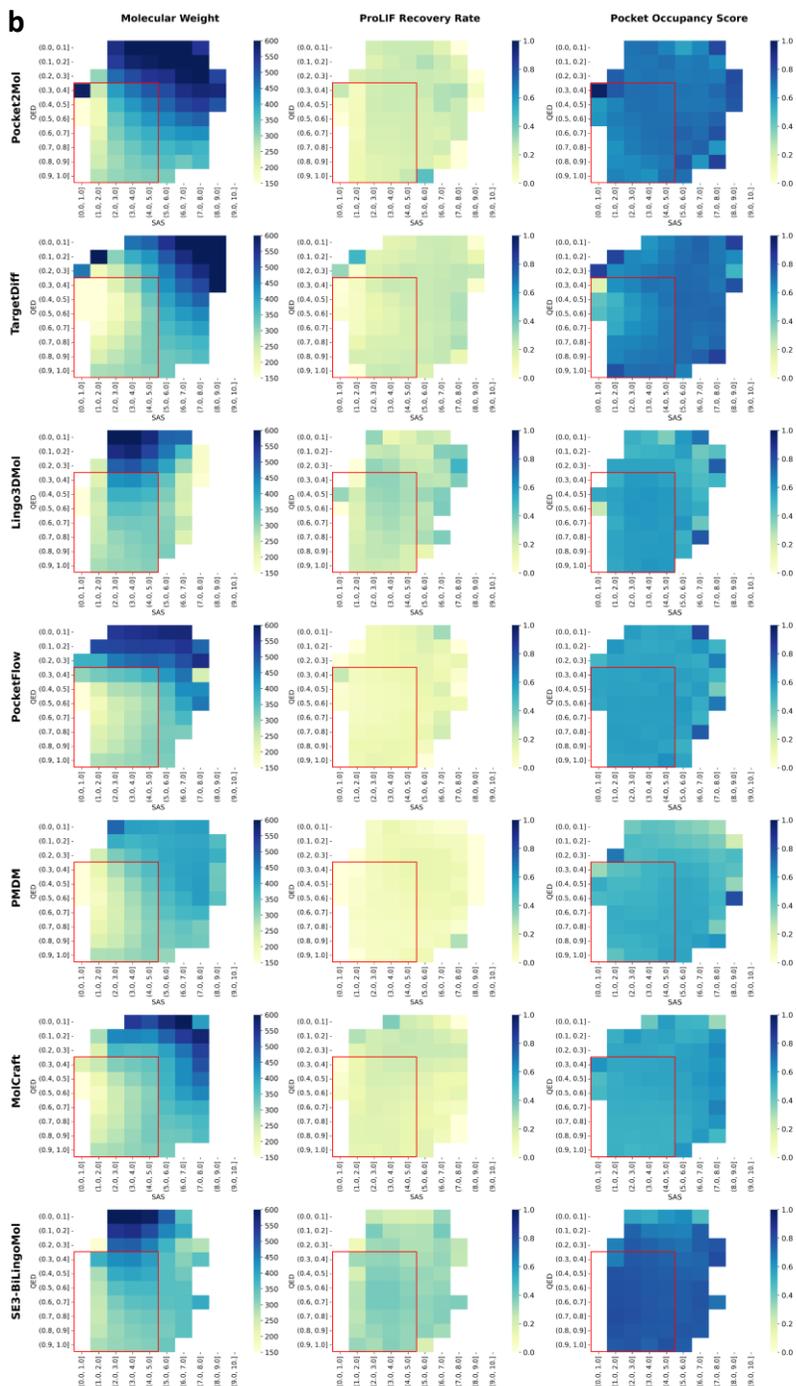

153 (xv) **Mean Pocket occupancy**. The score represents the weighted average occupancy  
154 similarity between generated ligands and the co-crystal ligand within the binding pocket,  
155 evaluated across multiple targets. To compute this score, the solvent-accessible surface  
156 area (SASA) difference between the unbound pocket (defined as all residues within 6 Å  
157 from its cocrystal ligand) and the ligand-bound complex is calculated for both the co-  
158 crystal ligand and each generated ligand. The occupancy of a given ligand is then defined  
159 as the ratio of its SASA difference to that of the co-crystal ligand, with values exceeding 1  
160 clipped to 1.

161 (xvi) **% ECFP\_TS>0.5**. The ratio of number of targets, where at least one generated  
162 druglike molecule exhibits a Tanimoto similarity > 0.5 based on the ECFP4 fingerprints  
163 with that of any known active compound for that target, over 102 targets. For the active  
164 compounds, we only considered those with docking score < -5; for drug-like molecule  
165 candidates, those with QED > 0.3, SAS < 5 and min-in-place score < 0 are considered.

166

## 2.2 Property Distributions of Generated molecules across QED and SAS

169

170 **Supplementary Information Figure S1.** Property distributions of generated molecules across  
 171 QED and SAS. This figure illustrates the distributions of various molecular properties for molecules  
 172 generated across DUD-E 102 targets. A drug-like region, defined as QED > 0.3 and SAS < 5,  
 173 is highlighted by a red box. The analysis encompasses around 1000 molecules generated per target  
 174 across the 102 DUD-E targets for each model under evaluation.

175 (a) Distributions of number of generated molecules, min-in-place score, and redocking score.

176 (b) Distributions of molecular weight, ProLIF recovery rate, and pocket occupancy score.

## 177 3. HPK1 Novel Hit Scaffold Discovery

### 178 3.1 Screening Pipeline for Generated Molecules

179 To identify novel hit scaffolds, generated molecules underwent a multi-stage filtering  
180 pipeline followed by a clustering module. The filtering pipeline comprised several  
181 submodules, each with a pre-defined passing rate tailored to reflect specific screening  
182 objectives (as discussed subsequently). Filtering criteria were set to achieve these desired  
183 passing rates. The passing rate for each submodule, calculated as the proportion of all  
184 generated molecules (totaling approximately 1.2 million) satisfying its respective criterion,  
185 along with the associated criteria, are detailed below:

186 (i) **Binding Quality Measurement via Minimum-in-Place GlideSP Score.** The min-  
187 in-place docking score was calculated using the "mininplace" method within the  
188 Schrödinger Glide module. Molecules with a min-in-place score less than -8 were retained,  
189 resulting in a 10% passing rate.

190 (ii) **Evaluation of Ligand-Pocket Complementarity Using ExptGMS.** The electron  
191 density of a reference ligand-protein complex (PDB ID 7KAC) was utilized, and the  
192 complementarity score at 3.0 Å resolution (ed30\_score) was predicted for each molecule.  
193 A threshold of ed30\_score > 24,000 was applied to indicate favorable complementarity,  
194 leading to a 60% passing rate.

195 (iii) **Estimation of Occupancy within L23-G24-G25 Region.** For each generated  
196 ligand, the residue-level Solvent Accessible Surface Area (SASA) of L23, G24, and G25  
197 in the bound protein state was calculated. These values were then compared to their  
198 unbound state to determine a SASA difference, indicative of each residue's contact with  
199 the ligand. Specifically, molecules exhibiting contact with L23 > 65 Å<sup>2</sup> and G24 > 8 Å<sup>2</sup>  
200 were considered to possess good sub-pocket occupancy, yielding a 40% passing rate.

201 (iv) **Conformational Validity Assessment via Torsional Energy Descriptor (TED).**  
202 The torsional energy of various dihedral angles was assessed for each generated ligand. A  
203 strict criterion was applied, retaining only molecules with a low torsional energy (<2  
204 kcal/mol), which yielded a 40% passing rate.

205 (v) **Drug-Likeness Assessment (QED and SAS).** Molecules were filtered based on  
206 QED > 0.3 and SAS < 5, resulting in a 90% passing rate.

207 (vi) **Molecular Weight (MW) Compliance.** Molecules with molecular weights  
208 outside the range of 300 to 550 Da were excluded, leading to a 95% passing rate.

209 (vii) **Number of Rotatable Bonds < 6.** To promote higher molecular rigidity, the  
210 maximum allowed number of rotatable bonds was set to 5. This criterion resulted in a 60%  
211 passing rate.

212 The rationale behind the establishment of passing rates and the selection of specific  
213 thresholds for each filter was guided by the objective of novel scaffold discovery. At this  
214 initial stage, general drug-likeness metrics, including QED, SAS, and MW, were  
215 deliberately set to be less stringent, allowing over a 90% passing rate for each. This  
216 approach, aimed at maximizing the initial diversity of generated scaffolds, ensured that  
217 only a minor proportion of molecules were excluded based on these generalized criteria. In  
218 contrast, to identify novel scaffolds with a desired binding mode, more rigorous thresholds  
219 were applied for sub-pocket occupancy (L23-G24-G25) and pocket binding quality  
220 (minimum-in-place GlideSP score), achieving 40% and 10% passing rates, respectively.  
221 The torsional energy threshold was derived from prior work<sup>9,10</sup>, yielding a 40% passing

222 rate. The number of rotatable bonds was optimized empirically: a setting exceeding 7 was  
223 observed to introduce undesirable aliphatic chains containing consecutive  $sp^3$  carbons. The  
224 ExptGMS threshold was set to exclude molecules with extreme overall shapes, thereby  
225 preventing an excessively high exclusion rate.

226 This filtering pipeline successfully identified 7,224 molecules, which were then  
227 clustered into 200 groups using a spectral clustering algorithm. Specifically, this algorithm  
228 operated on a similarity matrix derived from computing the maximum common  
229 substructure (MCS) of pairwise Bemis-Murcko (BM) scaffolds. Here, MCS of BM  
230 scaffolds were employed instead of Tanimoto similarity of entire molecules' ECFP4  
231 fingerprints because the high diversity observed among molecules generated at this stage  
232 resulted in low similarity between most of the given pairs, which made the similarity  
233 matrix-based clustering inefficient for whole molecules. Finally, for each cluster, molecule  
234 with best (lowest) min-in-place GlideSP score was selected as the representative of this  
235 group.

## 236 3.2 Molecules Resulting from Screening Pipeline

237 The generated molecules selected from the screening pipeline are listed in the  
238 [Supplementary Files](#) within the Figshare repository (released\_data →  
239 [RoundI\\_Scaffold\\_Discovery\\_Filtered\\_Representative\\_200\\_Molecules.sdf](#))  
240

## 241 4. HPK1 Lead Compound Optimization

### 242 4.1 Screening Pipeline for Generated Molecules

243 During our lead optimization stage, where drug-likeness and the mitigation of  
244 aromaticity were prioritized over novelty, the molecular filtering pipeline underwent  
245 several modifications. Specifically, an increased focus was placed on critical chemical  
246 properties, necessitating more stringent thresholds for QED, SAS, MW, and the number of  
247 rotatable bonds. Furthermore, the fraction of  $sp^3$ -hybridized carbons (F $sp^3$ ) and the number  
248 of aromatic rings were incorporated as additional filters to actively reduce the aromaticity  
249 of the compliant compounds. For binding mode filtering, the shared scaffold structure of  
250 regions A and C in the generated molecules rendered the general binding quality metrics,  
251 such as the min-in-place GlideSP score and ExptGMS, inefficient for evaluating subtle  
252 binding mode variations. Consequently, the thresholds for these two metrics were adjusted  
253 to reduce the exclusion rate and avoid discarding potentially valuable compounds. In  
254 contrast, because we particularly focused on the modifications in region B, the fulfillment  
255 of two critical NCIs observed in the Cmpd. 2-HPK1 crystal structure was rigorously  
256 monitored: a  $\pi$ -stacking interaction with Y28 and a hydrogen bond with K46.

257 The revised filtering pipeline comprised the following submodules. For each  
258 submodule, the passing rate was calculated as the proportion of all generated molecules  
259 (totaling approximately 0.2 million) satisfying its respective criterion:

260 (i) **Binding Quality Measurement via Minimum-in-Place GlideSP Score:** Molecules  
261 exhibiting a minimum-in-place GlideSP score of  $< -7$  were considered, applying a  
262 relatively permissive criterion. This initial screening yielded a 90% passing rate.

263 (ii) **Evaluation of Ligand-Pocket Complementarity Using ExptGMS:** Instead of  
264 relying on PDB ID 7KAC, the electron density of the ligand-protein complex (PDB ID

265 9WD3) served as a reference for predicting the ed30\_score for each molecule. An  
266 ed30\_score > 18,450 filtering criteria was used to achieve a 95% passing rate.

267 (iii) **Fulfillment of Key NCIs (Y28 and K46)**: ProLIF was utilized to identify generated  
268 molecules forming either a  $\pi$ -stacking interaction with Y28 or a hydrogen bond with K46.  
269 This criterion yielded a 50% passing rate.

270 (iv) **Conformational Validity Assessment via TED**: Only molecules possessing valid  
271 torsional energy across all torsion dihedrals were considered, resulting in a 50% passing  
272 rate.

273 (v) **Mitigation of Aromaticity and Planarity**: To address potential cytotoxicity  
274 associated with excessive aromaticity and planarity observed in Cmpd. 4, metrics such as  
275 Fsp3 and the number of aromatic rings were integrated into the screening criteria.  
276 Molecules with Fsp3 > 0.35 were selected, referencing Fsp3 values of SW898 (0.19),  
277 Cmpd. 2 (0.27), and Cmpd. 4 (0.29). This filter resulted in an 80% passing rate.

278 (vi) **Number of Aromatic Rings < 4**: Molecules with fewer than 4 aromatic rings were  
279 considered, yielding a 90% passing rate.

280 (vii) **Number of Rotatable Bonds < 5**: To maintain relatively higher rigidity, the  
281 maximum allowed number of rotatable bonds was set to 4. This criterion resulted in a 70%  
282 passing rate.

283 (viii) **MW Compliance**: Molecules with molecular weights outside the range of 300 to  
284 530 were excluded, with a 90% passing rate.

285 (ix) **Drug-Likeness Assessment (QED and SAS)**: More stringent criteria were applied  
286 for drug-likeness, specifically QED > 0.35 and SAS < 4.5, leading to a 50% passing rate.

287 Collectively, these filtering steps yielded a final set of 14,864 generated molecules.  
288 Subsequently, these molecules were grouped into 200 clusters using a spectral clustering  
289 algorithm. The input similarity matrix for clustering was computed based on the pairwise  
290 Tanimoto similarity of ECFP4 molecular fingerprints. For each cluster, the representative  
291 molecule was selected as the one exhibiting the highest Fsp3 value among its group  
292 members.

## 293 4.2 Molecules Resulting from Screening Pipeline

294 The generated molecules selected from the screening pipeline are listed in the  
295 [Supplementary Files](#) within the Figshare repository (released\_data →  
296 [RoundII\\_Lead\\_Optimization\\_Filtered\\_Representative\\_200\\_Molecules.sdf](#)).

## 298 5. *In Vitro* and *In Vivo* Assays

### 299 5.1 HPK1 ADP-Glo Kinase Assay

300 HPK1 inhibitory activities were determined using the ADP-Glo kinase assay at 40  $\mu$ M  
301 ATP. Initially, 8  $\mu$ L of compounds were transferred to a 384-well LDV Echo plate.  
302 Subsequently, compounds were diluted and 50 nL aliquots were dispensed into a Greiner  
303 white assay plate using an Echo liquid handler, yielding 10 concentration points in  
304 duplicate (starting from a top concentration of 49.5  $\mu$ M with 3-fold serial dilutions). The  
305 enzyme was prepared in assay buffer to a final concentration of 5 nM. A 2.5  $\mu$ L aliquot of  
306 the enzyme mixture was added to each well of the assay plate. The plate was then spun  
307 down at 1000 rpm, centrifuged for 30 seconds, and pre-incubated for 15 minutes at 25°C.

308 A substrate mixture was prepared, and 2.5  $\mu\text{L}$  was added to a Corning 4512 assay plate to  
309 initiate the reaction. The plate was then briefly centrifuged at 1000 rpm for 30 seconds to  
310 ensure all reagents were at the bottom of the wells and properly mixed, and then incubated  
311 at 25°C for 90 minutes. Following the 90-minute incubation, 5  $\mu\text{L}$  of ADP-Glo™ Reagent  
312 was added. The plate was incubated at room temperature for 60 minutes, after which 10  $\mu\text{L}$   
313 of Kinase Detection Reagent was added. A final incubation at room temperature was  
314 performed for another 60 minutes. Finally, luminescence was recorded using an Envision  
315 plate reader. The 50% inhibitory concentration ( $\text{IC}_{50}$ ) values were subsequently calculated  
316 using the log (inhibitor) vs. normalized response–variable slope model provided by  
317 GraphPad Prism.

## 318 **5.2 HPK1 HTRF Kinase Assay**

319 HPK1 inhibitory activities were determined using the HTRF Assay at 1 mM ATP.  
320 Initially, 10  $\mu\text{L}$  of compounds were transferred to a 384-well LDV Echo plate.  
321 Subsequently, compounds were diluted, and 100 nL aliquots were dispensed into a Greiner  
322 white assay plate using an Echo liquid handler, yielding 10 concentration points in  
323 duplicate. The enzyme was prepared in assay buffer to a final concentration of 5 nM. A 5  
324  $\mu\text{L}$  aliquot of the enzyme mixture was added to each well of the assay plate. The plate was  
325 then spun down at 1000 rpm, centrifuged for 30 seconds, and pre-incubated for 15 minutes  
326 at 25°C. A substrate mixture was prepared, and 5  $\mu\text{L}$  was added to a Corning 784075 assay  
327 plate to initiate the reaction. The plate was then briefly centrifuged at 1000 rpm for 30  
328 seconds to ensure all reagents were at the bottom of the wells and properly mixed, and then  
329 incubated at 25°C for 16 hours. Following the 16-hour incubation, 10  $\mu\text{L}$  of the XL665 and  
330 antibody detection reagent mixture was added. The plate was incubated for 120 minutes at  
331 room temperature. Finally, the TR-FRET signal (665/612 nm) was recorded using an  
332 Envision plate reader.

## 333 **5.3 Kinase Selectivity Assays**

334 Kinase activity inhibition was assessed using the KinaseProfiler (Eurofins Discovery,  
335 France) at 10  $\mu\text{M}$  ATP. This platform utilizes a radiometric assay to measure the  
336 inhibition of kinase catalytic activity.  
337

## 338 **5.4 Jurkat pSLP76 Cellular Assay**

339 Jurkat E6-1 cells were cultured overnight in RPMI 1640 medium supplemented with  
340 0.5% Fetal Bovine Serum (FBS). Following overnight culture, 30  $\mu\text{L}$  of cells ( $0.3 \times 10^6$   
341 cells) were added per well to the assay plate. The test compounds were prepared via a three-  
342 fold serial dilution. Then, 7.5  $\mu\text{L}$  of each diluted compound was transferred to the assay  
343 plate, resulting in 10 concentration points in duplicate. The plate was subsequently  
344 incubated for 4 hours in a 37°C incubator with 5%  $\text{CO}_2$ . After this initial incubation, 7.5  
345  $\mu\text{L}$  of 6 $\times$  anti-human CD3 antibody was added to each well, and the plate was incubated  
346 for an additional 20 minutes in a 37 °C incubator with 5%  $\text{CO}_2$ . Finally, phosphorylated  
347 SLP-76 (S376) levels were determined using a Cisbio HTRF assay kit. Based on these  
348 results, the  $\text{IC}_{50}$  values of the compounds were calculated.

## 349 **5.5 Human T-cell IL-2 Induction Assay**

350 Human primary T cells were isolated from human peripheral blood mononuclear cells  
351 (PBMCs) using a human T cell isolation kit (Miltenyi Biotec, CAT: 130-096-535). Isolated  
352 T cells were plated in 96-well plates and pre-treated with varying concentrations of test  
353 compounds for 30 minutes. Subsequently, the cells were stimulated with 0.5 µg/mL anti-  
354 human CD3 antibody and 0.5 µg/mL anti-human CD28 antibody for 48 hours. Following  
355 the stimulation, cell culture supernatants were harvested and analyzed for IL-2 release  
356 using an ELISA kit.

## 357 **5.6 Cell Viability Assay**

358 HepG2 cells were cultured and assayed in EMEM medium supplemented with 10%  
359 FBS. After seeding into 96-well plates and incubating overnight in a 37 °C incubator with  
360 5% CO<sub>2</sub>, cells were treated with the indicated concentrations of test compounds for 72  
361 hours. Cell viability was subsequently measured using the CellTiter-Glo® Luminescent  
362 (CTG) assay.

363 To assess the direct antiproliferative or cytotoxic effect of the compounds on CT26  
364 tumor cell lines, a CTG assay was performed according to the manufacturer's instructions  
365 (Promega #G7573). CT26 cells were cultured in RPMI 1640 medium supplemented with  
366 10% FBS, seeded into 384-well plates, and incubated overnight in a 37 °C incubator with  
367 5% CO<sub>2</sub>. Cells were subsequently treated with the indicated concentrations of test  
368 compounds for 72 hours, and cell viability was measured using the CTG assay.

## 369 **5.7 CT26 Murine Syngeneic Model Efficacy Studies**

370 All animal studies were conducted at ProOnco Therapeutics Co., Ltd, and were  
371 approved by the Institutional Animal Care and Use Committee (IACUC, permit: IACUC-  
372 ALM-01). CT26 tumor cells were maintained *in vitro* in RPMI 1640 medium supplemented  
373 with 10% FBS at 37°C in a 5% CO<sub>2</sub> atmosphere. For *in vivo* studies, BALB/c mice were  
374 subcutaneously inoculated in their right flank regions with  $3 \times 10^5$  CT26 tumor cells  
375 suspended in 0.1 mL of phosphate-buffered saline (PBS). Drug treatments were initiated  
376 when tumor volumes reached approximately 50–60 mm<sup>3</sup>. All enrolled tumor-bearing mice  
377 were randomized based on tumor size and body weight and then allocated to study groups.  
378 Test compounds were administered orally as a homogeneous suspension. Anti-mouse PD-  
379 1 (clone RMP1-14, Bio X Cell) was administered intraperitoneally (i.p.) as a solution.  
380 Study animals were monitored daily for signs of morbidity and mortality. Body weight and  
381 tumor volumes were measured every 2–3 days. Tumor volumes were determined in two  
382 dimensions using a caliper and expressed in mm<sup>3</sup> according to the formula:  $V = (L \times W \times$   
383  $W) / 2$ , where V represents tumor volume, L is the longest tumor dimension, and W is the  
384 longest tumor dimension perpendicular to L. The experiment was terminated with all  
385 individual animals euthanized when the mean tumor volume of the control group exceeded  
386 2,000 mm<sup>3</sup>.  
387

## 388 **5.8 Solubility Assay**

389 Kinetic solubility was measured in various standard pH buffers (pH 6.5, pH 7.4).

390 Initially, 2  $\mu\text{L}$  of a DMSO stock solution containing the test compound was added to 198  
391  $\mu\text{L}$  of the respective buffer, followed by thorough mixing. The samples were then shaken  
392 for 4 hours in an Eppendorf ThermoMixer at 350 rpm and 25°C. Subsequently, samples  
393 were filtered through a filter plate. The resulting filtrate was diluted with DMSO according  
394 to the established dilution scheme (details to be provided in supplementary methods if  
395 complex). Finally, 5  $\mu\text{L}$  of the diluted sample solutions and calibration standard solutions  
396 were spiked into 300  $\mu\text{L}$  of quenching solution, mixed thoroughly, and prepared for  
397 subsequent LC/MS analysis.

## 398 **5.9 Caco-2 Permeability**

399 The bi-directional apparent permeability of test compound was determined using a  
400 Caco-2 monolayer cell model. Caco-2 cells (50  $\mu\text{L}$  of cell suspension at a density of  $6.86$   
401  $\times 10^5$  cells/mL) were seeded onto Transwell inserts. These cells were cultured for 14–18  
402 days to form a confluent cell monolayer. The test compound was subsequently added to  
403 either the apical or basolateral side of the cell monolayer. The system was then incubated  
404 at 37°C for up to 2 hours to facilitate bi-directional transport. Samples were processed and  
405 analyzed by LC-MS/MS. Finally, the bi-directional apparent permeability, efflux ratio, and  
406 system recovery were calculated.

## 407 **5.10 Hepatocyte Stability Assay**

408 The metabolic stability of test compound was assessed using hepatocyte suspensions  
409 from mouse, rat, dog, and human. Hepatocyte suspensions from the four species, each  
410 containing 1  $\mu\text{M}$  of test compound, were incubated in an orbital shaker at 37°C for up to  
411 120 minutes. Cell aliquots of 25  $\mu\text{L}$  were removed at time points of 0, 15, 30, 60, 90, and  
412 120 minutes. To terminate the metabolic reaction, these aliquots were immediately mixed  
413 with 6 volumes (150  $\mu\text{L}$ ) of acetonitrile containing internal standards (i.e. 100 nM  
414 alprazolam, 200 nM labetalol, 200 nM caffeine, and 2  $\mu\text{M}$  ketoprofen). The plate was then  
415 centrifuged for 20 minutes at  $3,220 \times g$ . A 100  $\mu\text{L}$  aliquot of the resulting supernatant was  
416 mixed with 100  $\mu\text{L}$  of ultra-pure  $\text{H}_2\text{O}$  and subsequently used for LC-MS/MS analysis.  
417

## 418 **5.11 Plasma Protein Binding**

419 The plasma protein binding of test compound in plasma from mice, rats, dogs, and  
420 humans was determined by equilibrium dialysis. Plasma samples from each species,  
421 containing 1  $\mu\text{M}$  of test compound and the control compound ketoconazole, were added to  
422 a HTD 96-well dialysis device. The device was then incubated at 37°C with 5%  $\text{CO}_2$  at  
423 100 rpm for 6 hours. Following incubation, the samples were processed, and the  
424 concentrations of test compound were determined by LC-MS/MS. This data was then used  
425 to calculate the bound fraction, fraction unbound, and system recovery.

## 426 **5.12 PXR Activation in DPX2 Cells**

427 DPX2 cells were seeded into 384-well plates at a density of  $1 \times 10^4$  cells/well and  
428 incubated for 24 hours at 37°C with 5%  $\text{CO}_2$ . Following incubation, the plates were  
429 removed from the incubator. Subsequently, 25 nL of the negative control, inducers, test  
430 compound (at concentrations of 1  $\mu\text{M}$  and 10  $\mu\text{M}$ ), and the positive control rifampicin (10

431  $\mu\text{M}$ ) were added. The plates were then returned to the incubator for an additional 48 hours.  
432 Cell viability was determined using the CellTiter-Fluor Assay reagent, with fluorescent  
433 excitation and emission wavelengths of 400 nm and 505 nm, respectively. Subsequently,  
434 PXR activation was investigated by measuring luciferase activity with ONE-Glo reagent  
435 (Promega). PXR activation was expressed as the ratio of the average relative light units  
436 (RLU) from triplicate determinations at each dose of test compound to the average RLU  
437 from triplicate determinations obtained with the corresponding vehicle control.

### 438 **5.13 CYP Inhibition Assay**

439 The direct inhibition of test compound on five isoforms of cytochrome P450 (CYP1A2,  
440 CYP2C9, CYP2C19, CYP2D6, and CYP3A) was evaluated using human liver microsomes.  
441 Specific probe substrates for each CYP isoform (CYP1A2: 0.5  $\mu\text{M}$   $\alpha$ -naphthoflavone;  
442 CYP2C9: 10  $\mu\text{M}$  sulfaphenazole; CYP2C19: 1  $\mu\text{M}$  (+)-N-3-Benzylrivanol; CYP2D6: 0.5  
443  $\mu\text{M}$  quinidine; and CYP3A: 0.5  $\mu\text{M}$  ketoconazole) were mixed with 0.2 mg/mL human  
444 liver microsomes, containing 10  $\mu\text{M}$  of test compound, for each respective isoform  
445 inhibition assay. Following a pre-incubation in a water bath for 8 minutes at 37°C, NADPH  
446 solution was added to all incubation wells, and incubation continued at 37°C. The reaction  
447 was terminated by the addition of 400  $\mu\text{L}$  of methanol containing internal standards (i.e.  
448 100 nM alprazolam, 500 nM labetalol, and 2  $\mu\text{M}$  ketoprofen) at the designated time point  
449 (Panel 1: 5 minutes). Samples were then centrifuged at  $3,220 \times g$  for 40 minutes to  
450 precipitate proteins. Subsequently, 100  $\mu\text{L}$  of the supernatant was transferred to a new 96-  
451 well plate and mixed with 100  $\mu\text{L}$  of water for LC-MS/MS analysis.

### 452 **5.14 Time-dependent Inhibition (TDI) Assay**

453 The assay was performed in potassium phosphate buffer. Verapamil, a known  
454 CYP3A4/5 inhibitor, was utilized as a positive control to validate the incubation system.  
455 Test compound was diluted to achieve six concentration points, starting from a top  
456 concentration of 50  $\mu\text{M}$  with 4-fold serial dilutions. These dilutions were then incubated  
457 with midazolam (a substrate for CYP3A4/5) in human liver microsomes. The reaction was  
458 initiated by the addition of the coenzyme NADPH and incubated at 37°C for 30 minutes.  
459 To terminate the reaction, ice-cold acetonitrile containing an internal standard was added  
460 to the incubation system. The mixture was then vortexed for 1 minute and centrifuged at  
461 4,000 rpm for 15 minutes at 4°C. A 200  $\mu\text{L}$  aliquot of the resulting supernatant was then  
462 transferred and thoroughly mixed with 50  $\mu\text{L}$  of water. These samples were subsequently  
463 centrifuged again at 4,000 rpm for 5 minutes at 4°C prior to LC-MS/MS analysis.

### 464 **5.15 hERG Inhibition**

465 HEK 293-hERG cells (Invitrogen, Cat. K1236) were cultured in DMEM-based  
466 medium (85% DMEM, 10% dialyzed FBS, 0.1 mM NEAA, 25 mM HEPES, 100 U/mL  
467 Pen-Strep, 5  $\mu\text{g}/\text{mL}$  Blasticidin, 400  $\mu\text{g}/\text{mL}$  Geneticin) at 37°C, 5% CO<sub>2</sub>. hERG expression  
468 was induced with 1  $\mu\text{g}/\text{mL}$  doxycycline for 48 hours. For assay, cells (approx.  $5 \times 10^5$   
469 cells/3.5 cm dish) were plated on coverslips in Blasticidin/Geneticin-free medium. Whole-  
470 cell patch-clamp recordings utilized a PatchMaster system (HEKA Elektronik). A giga-  
471 ohm ( $G\Omega$ ) seal and whole-cell configuration were established via suction, with capacity  
472 currents compensated (Cfast/Cslow). Membrane potential was -60 mV. Holding potential:

473 -90 mV for 500 ms (20 kHz recording, 10 kHz filter). Leak current: -80 mV for 500 ms.  
474 hERG current was elicited by +30 mV for 4.8 s, then -50 mV for 5.2 s; tail current  
475 amplitude was measured. Current stability was confirmed for 120 s. After 5 min vehicle  
476 control baseline, test compound was applied. Steady-state hERG current was recorded for  
477 ~5 min (5 sweeps). Five cumulative concentrations of compound were tested for dose-  
478 response. Dofetilide (150 nM) served as an internal low control post-highest test compound.  
479 System validation included a full dofetilide dose-response (5 concentrations) on an  
480 identical cell batch.

## 481 **5.16 Animal Pharmacokinetic (PK) Studies**

482 For *in vivo* pharmacokinetic experiments, the test compound was administered to male  
483 CD1 mice and male Sprague Dawley rats either intravenously or via oral gavage. For  
484 intravenous (IV) dosing, the test compound was typically administered at a dose of 1 mg/kg  
485 as an IV bolus to both mice and rats. For oral (PO) dosing, the test compound was typically  
486 administered at a dose of 3.0 mg/kg. Blood samples were collected at pre-dose and at  
487 various specified time points up to 24 hours post-dose. All blood samples were collected  
488 using EDTA as the anticoagulant, and subsequently centrifuged to obtain plasma samples.  
489 The plasma concentrations of the test compound were determined using established LC-  
490 MS/MS methods. The measured plasma concentrations were then used to calculate  
491 pharmacokinetic (PK) parameters by applying standard noncompartmental analysis  
492 methods, utilizing the Phoenix® WinNonlin software program (version 8.0, Pharsight  
493 Corporation).  
494
