## Supplementary Notes

### Supplementary Note 1. Synthesis and characterization of PED, PEM

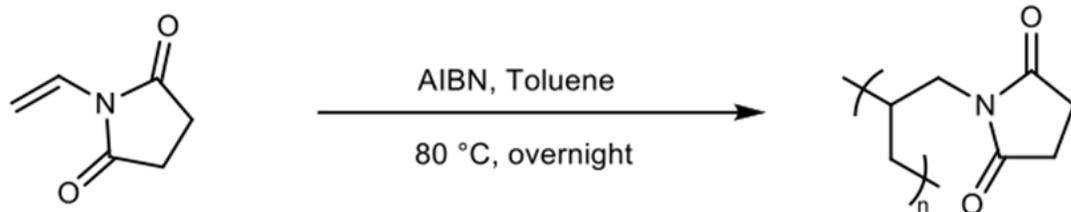

The detailed synthetic routes and characterizations of PED and PEM are shown in in Supplementary Scheme 1 and Supplementary Fig 1-4.

$^1\text{H}$  NMR spectra were measured on Bruker AdvanceCore 400 MHz NMR spectrometers. Gel permeation chromatography (GPC) were measured on Shimadzu model LG-2030C 3D.

### Supplementary Scheme. 1. Synthesis route of PED

Under a nitrogen atmosphere, 1-ethenylpyrrolidine-2,5-dione (ED) (0.2 mL) was dissolved in toluene (1 mL) together with 2,2'-azobis(2-methylpropionitrile) (AIBN, 0.002 mg). The solution was heated and stirred at 80 °C overnight to effect free-radical polymerization. To improve the solubility of the product, 1mL chloroform (CF) were added to the solution. The mixture was then poured into diethyl ether (DE) to precipitate the polymer. The resulting precipitated polymer was collected by filtration, purified by three cycles of reprecipitation (dissolution in CF followed by precipitation with DE, and dried under vacuum to constant mass. The PED sample was obtained as flake-like solids ( $M_n=5033$ ,  $M_w=7465$ ).

### Supplementary Scheme 2. Synthesis route of PEM

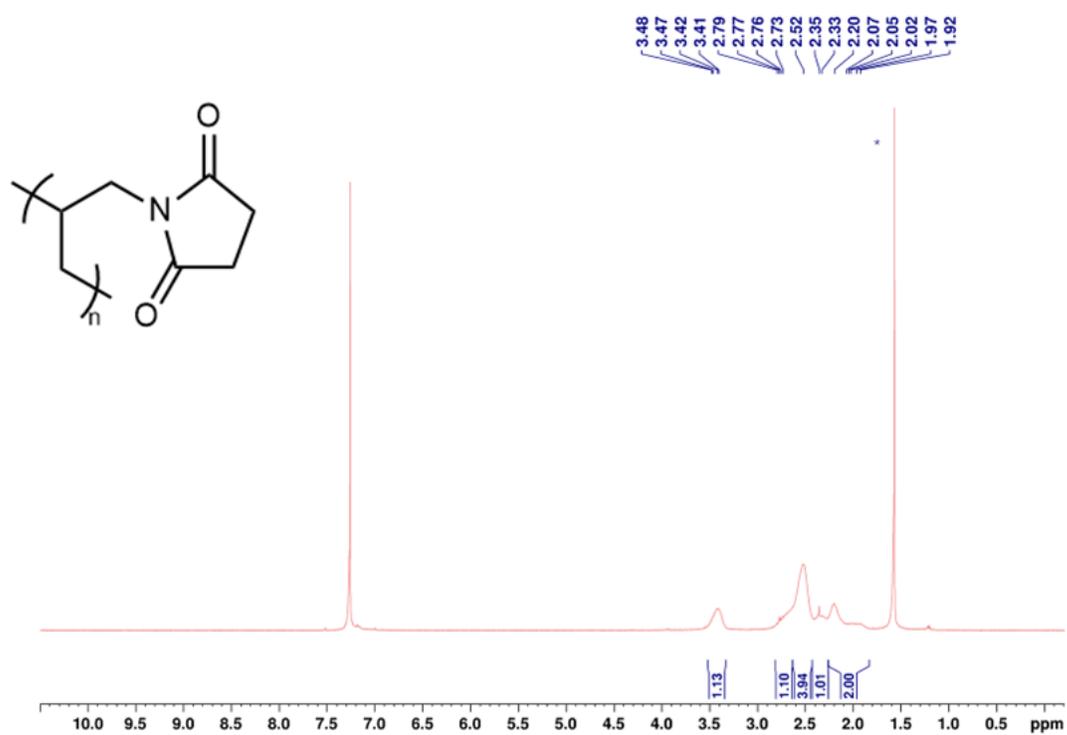

Similarly, under a nitrogen atmosphere, 1-ethenyl-3-methylpyrrolidin-2-one (EM) (0.2 mL) was dissolved in toluene (1 mL) together with AIBN (0.002 mg). The solution was heated and stirred at 80 °C overnight to effect free-radical polymerization. To improve the solubility of the product, 1 mL chlorobenzene (CB) was added to the solution. The mixture was then poured into diethyl ether (DE) to precipitate the polymer. The resulting precipitated polymer was collected by filtration, purified by three cycles of reprecipitation (dissolution in CB followed by precipitation with DE, and dried under vacuum to constant mass. The PEM sample appeared as a free-flowing granular powder ( $M_w=1577$ ,  $M_n=1600$ ).

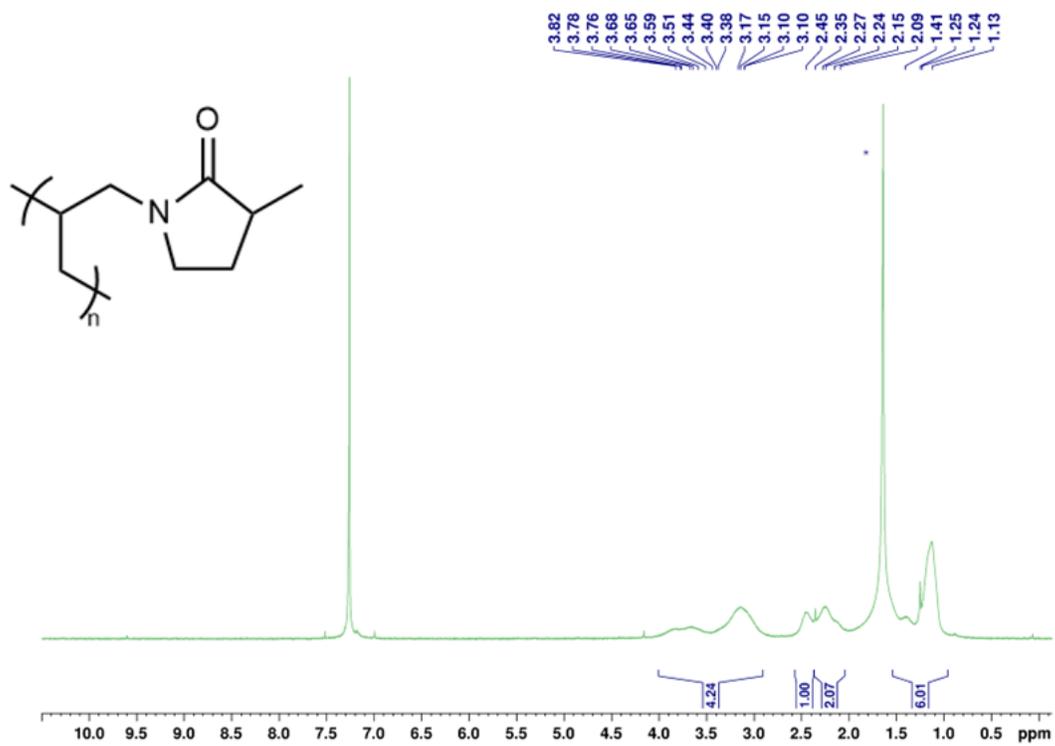

### **Supplementary Note 2. Perovskite thin-film peeling process**

The perovskite thin-film peeling process was performed as follows (process provided in **Supplementary Figure 27**). A uniform layer of A–B epoxy was first applied onto a clean glass substrate (Glass/FTO). The perovskite film was then placed with its top surface in direct contact with the epoxy layer and gently flipped or pressed to ensure complete adhesion. The assembly was left to cure for >8 h under ambient conditions. After curing, the two substrates were carefully separated, leaving the perovskite film adhered to the epoxy-coated glass. This configuration exposes the bottom interface of the perovskite layer for subsequent characterization.

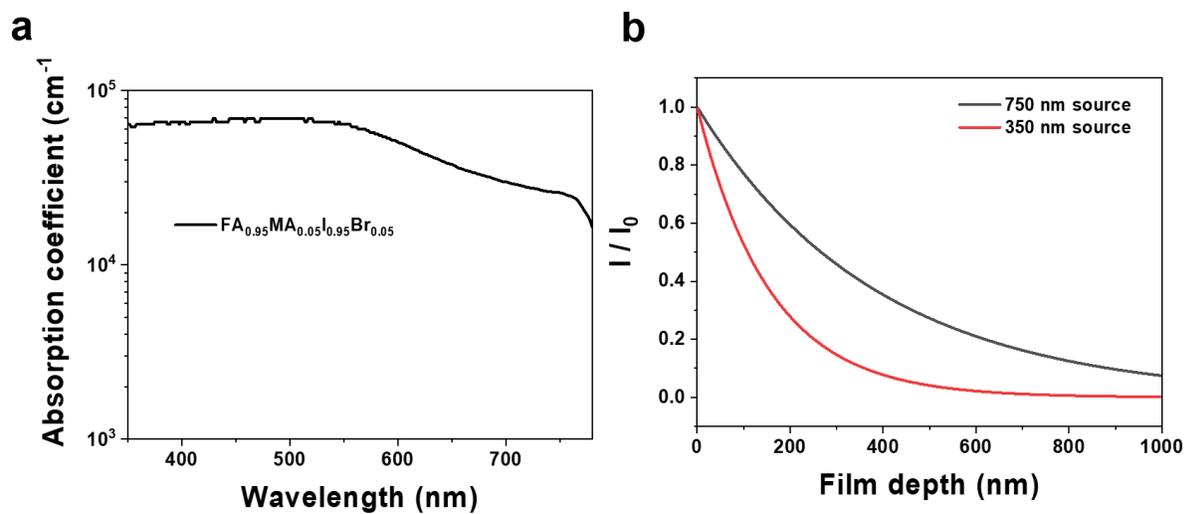

For complete device stacks, the top metal electrode was first removed using Kapton tape. The same peeling protocol described above was then applied to expose the buried perovskite/ETL interface.

## Supplementary Figures

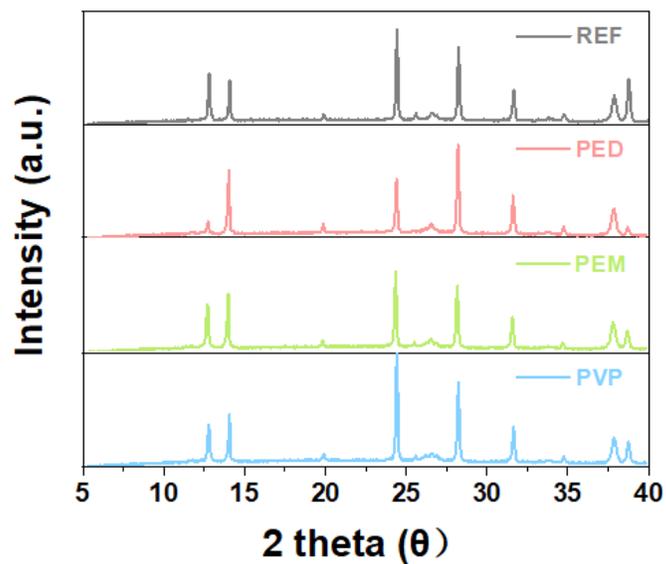

Supplementary Fig. 1. <sup>1</sup>H NMR of PED.

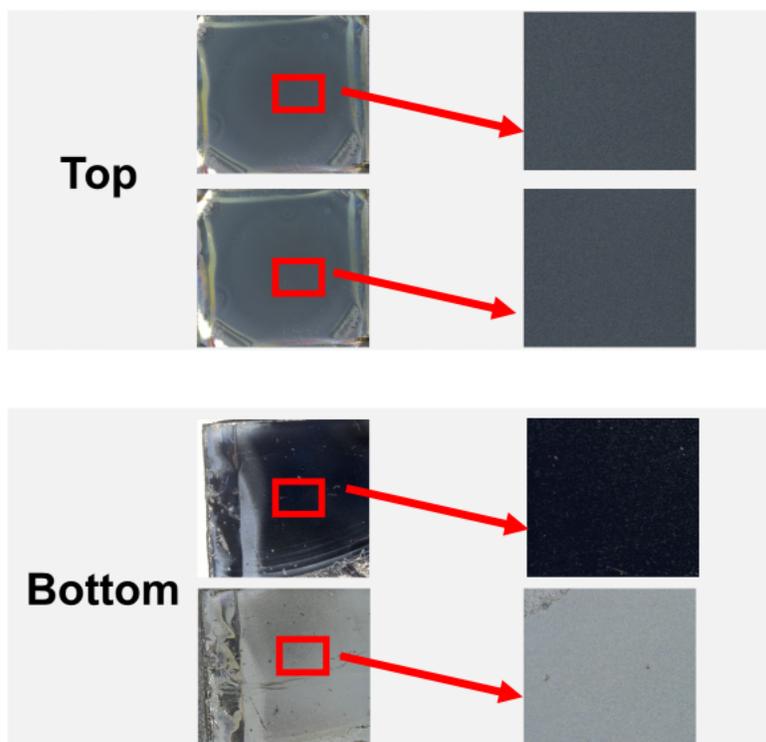

Supplementary Fig. 2. <sup>1</sup>H NMR of PED.

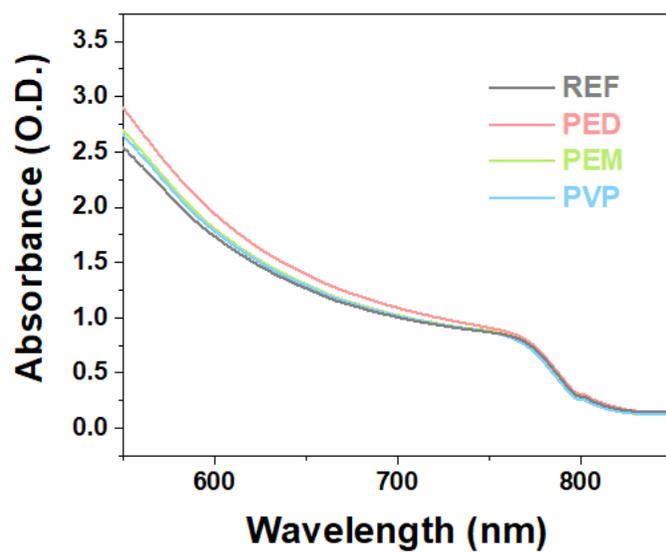

**Supplementary Fig. 3 Absorption spectra of perovskite film** (a) Absorption coefficient of FA<sub>0.95</sub>MA<sub>0.05</sub>I<sub>0.95</sub>Br<sub>0.05</sub>. (b) Depth dependent intensity attenuation of incident light ( $I_0$ ) with different light source wavelength.

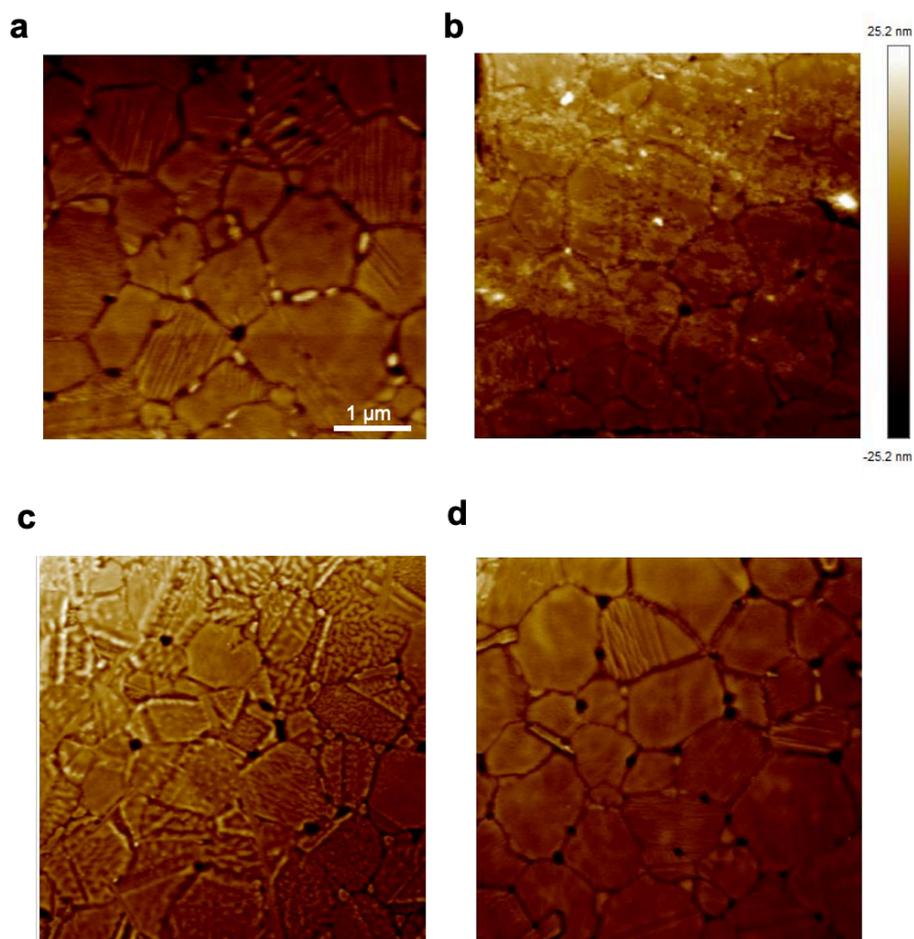

**Supplementary Fig.4 XRD spectra of fresh samples (X-ray incident from bottom interface).**

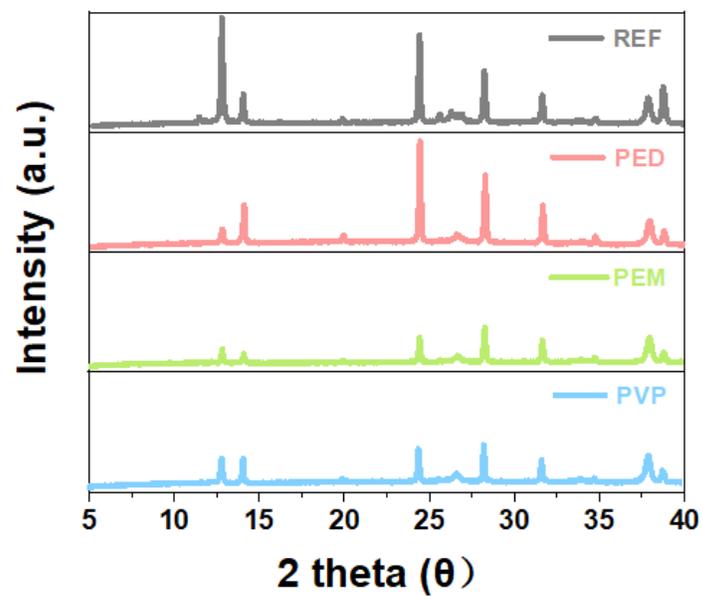

**Supplementary Fig. 5. Optical images of top and bottom interface comparison after incandescent lamp illumination aging under ambient condition (~40% humidity, room temperature).**

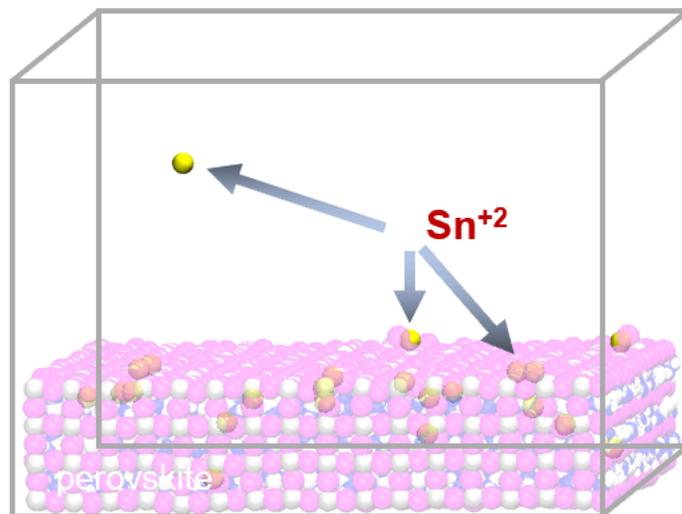

**Supplementary Fig. 6. UV-vis spectra of perovskite thin film deposited on ITO/(polymeric interlayers) substrate.**

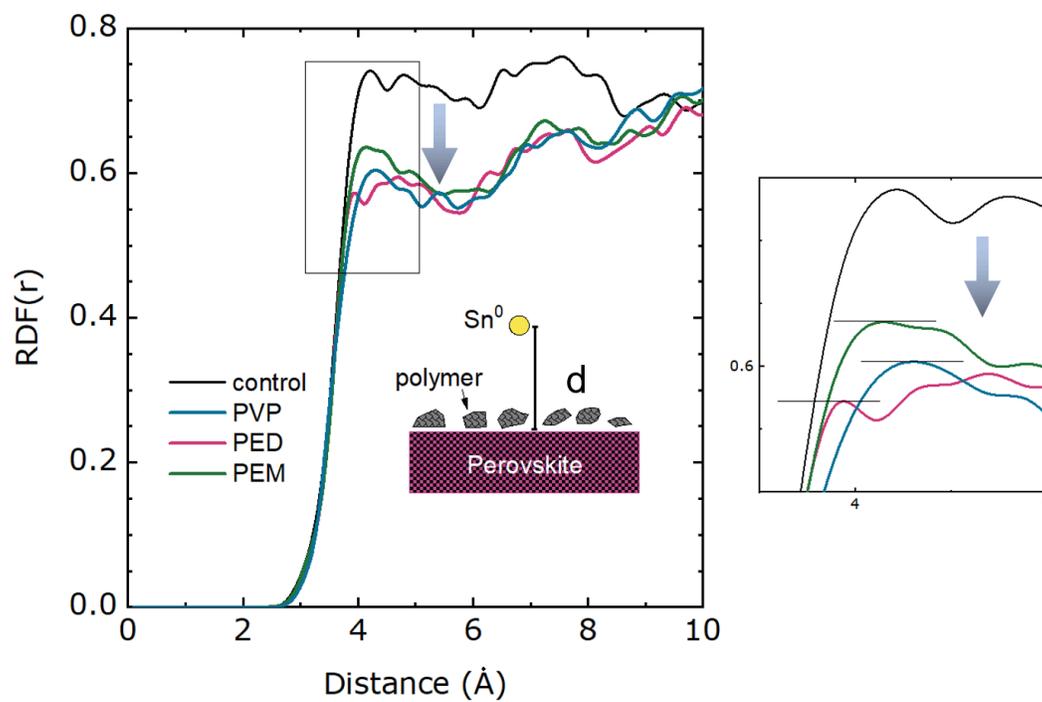

**Supplementary Fig. 7.** AFM images for bottom interface for fresh samples (a) REF(b) PED(c) PEM(d) PVP.

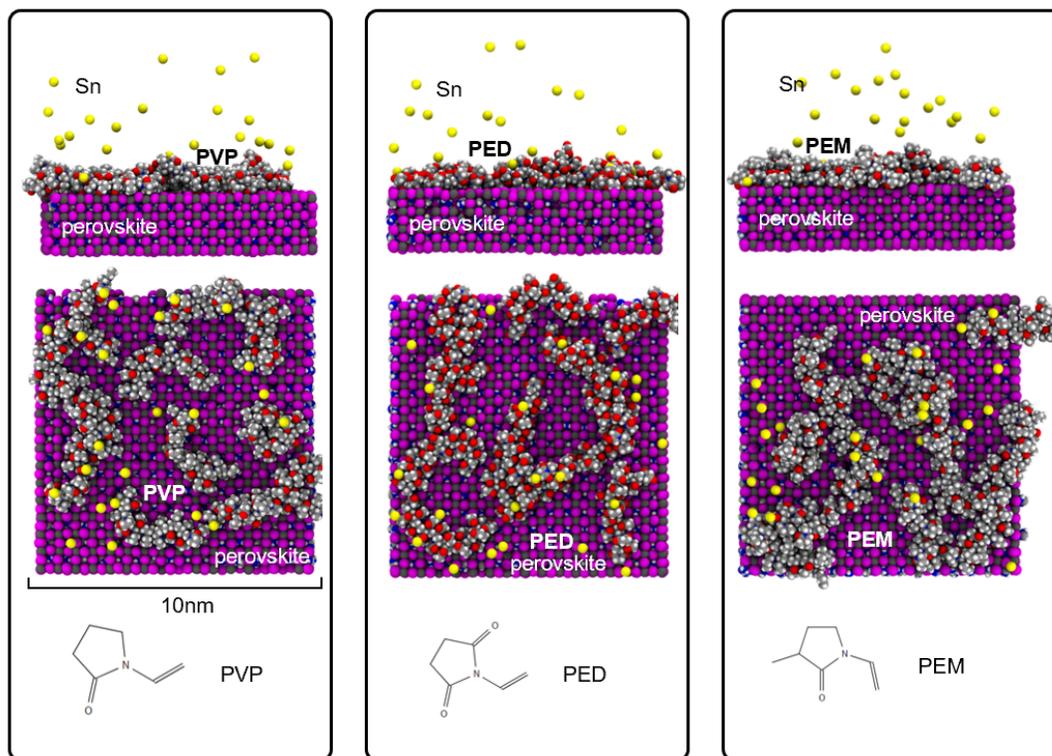

**Supplementary Fig. 8.** XRD spectra of aged samples (X-ray incident from bottom interface).

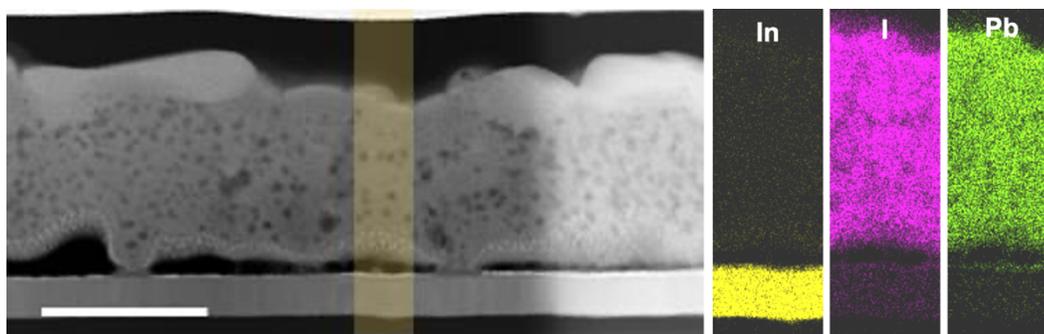

**Supplementary Fig. 9. Illustration of Sn migration near perovskite for MD simulations.**

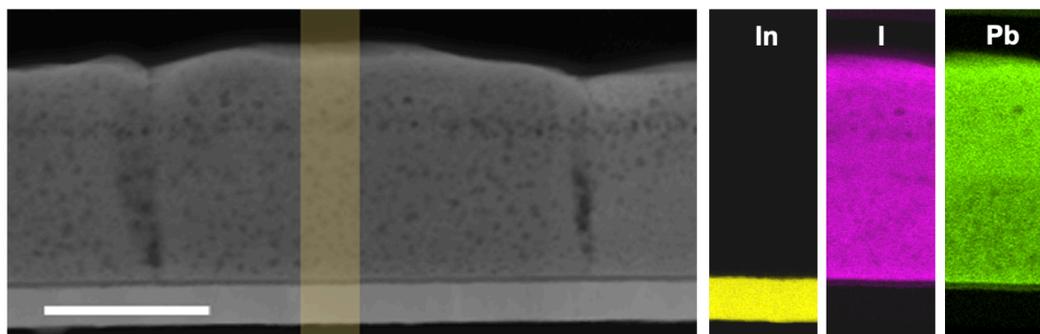

**Supplementary Fig. 10. MD simulations for the amount of Sn migration across different polymers.**

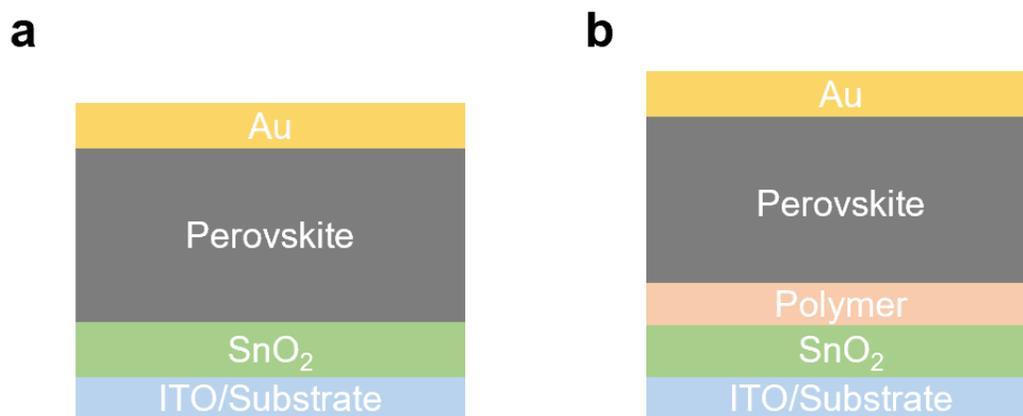

**Supplementary Fig. 11. Molecular Dynamic simulations for Sn migration across different polymers.**

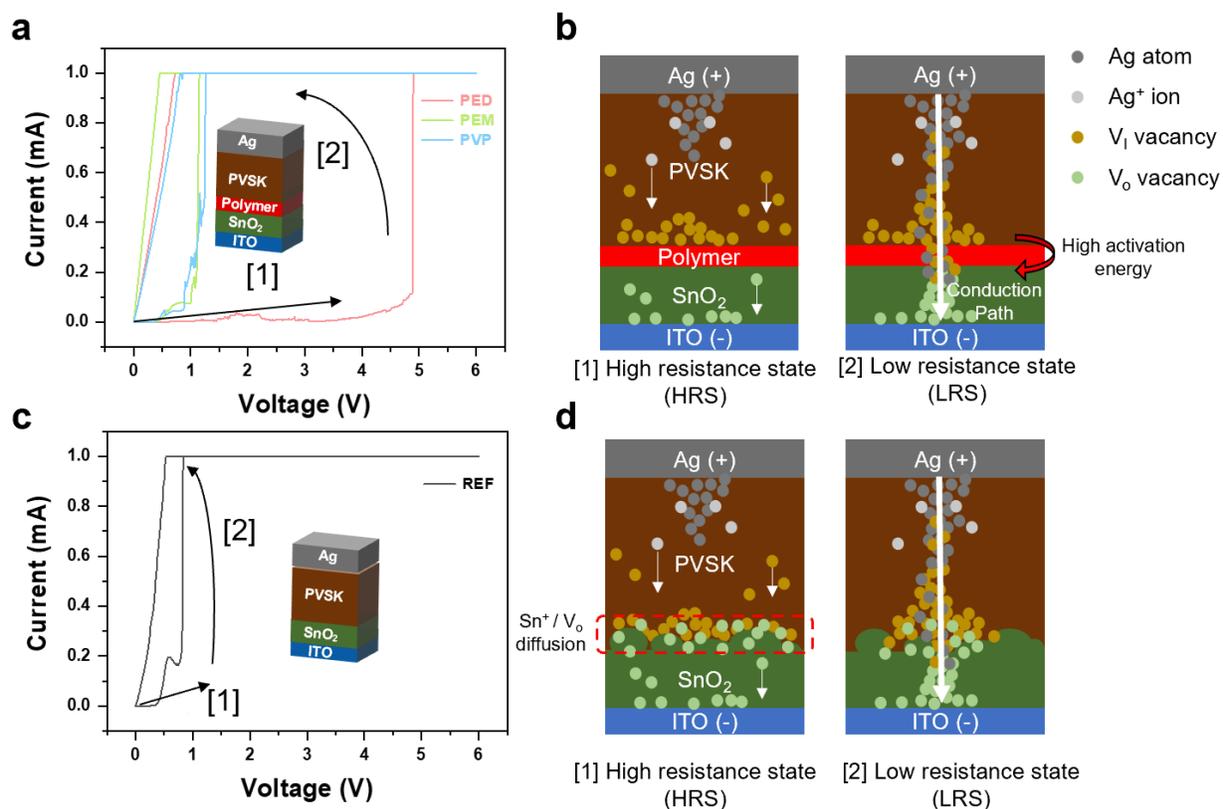

**Supplementary Fig. 12. STEM image (left) and EDS elemental maps (right) of In, I and Pb from the highlighted image area of an aging reference device.**

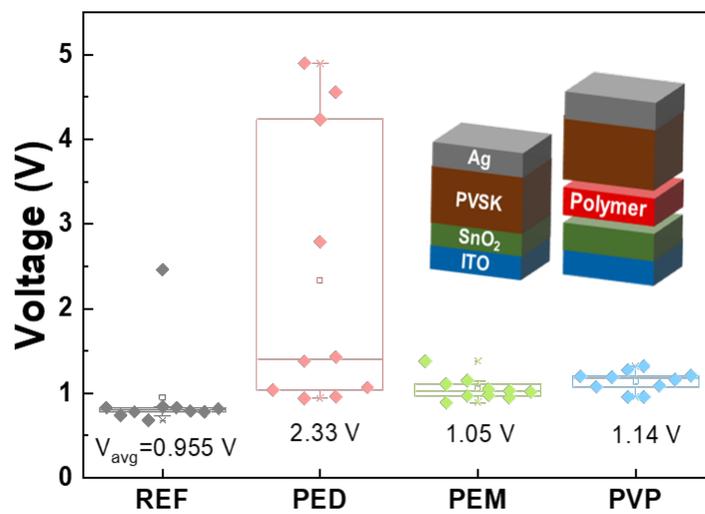

**Supplementary Fig. 13. STEM image (left) and EDS elemental maps (right) of In, I and Pb from the highlighted image area in an aging device with PED interlayer.**

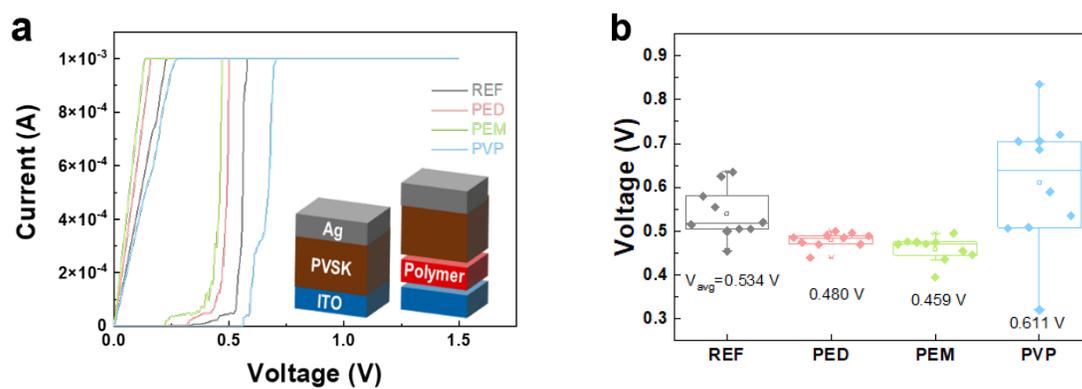

**Supplementary Fig. 14. Device illustration for temperature-dependent conductivity tests (a) reference device; (b) device with different polymeric interlayers**

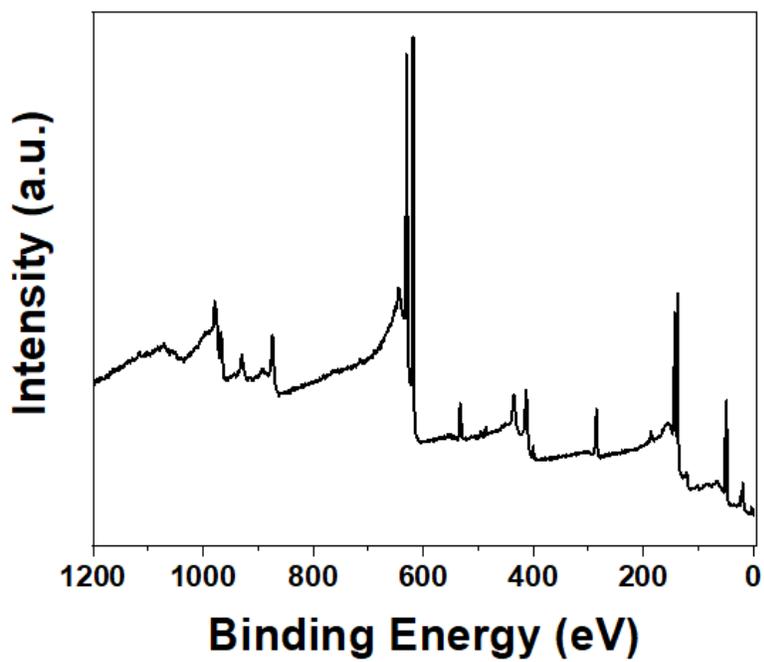

**Supplementary Fig. 15. I-V characteristics of resistivity switching test and corresponding schematics for (a,b) with polymeric interlayers and (c,d) without layers. For the region of [1], the conductive filament is not fully formed, maintaining high resistance state (HRS). The resistance state is abruptly switched to low resistance state (LRS) at the region [2] due to the formation of conductive filaments via mobile ion migrations.**

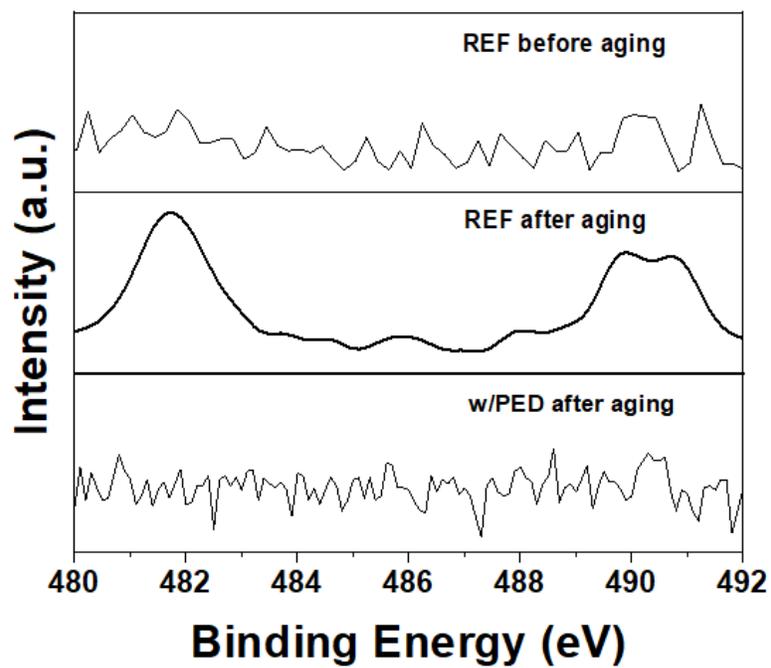

**Supplementary Fig. 16. Resistivity switching tests for polymeric interlayers with SnO<sub>2</sub>**  
(Extracted from 10 different cells)

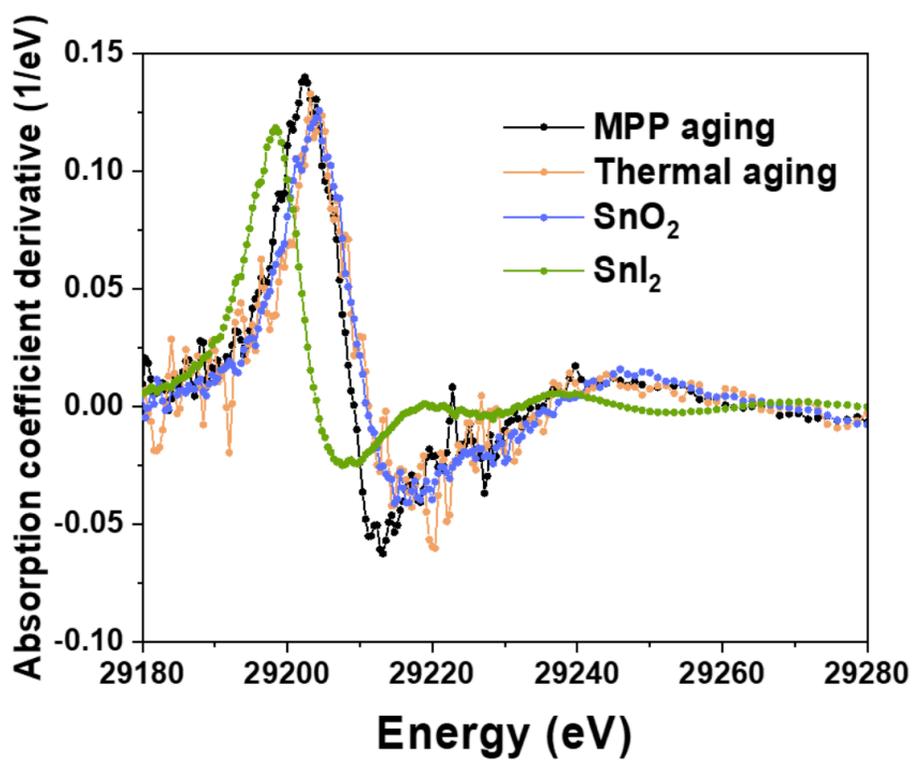

**Supplementary Fig. 17. Resistivity switching tests for polymeric interlayers without SnO<sub>2</sub>**  
(Extracted from 10 different cells).

Supplementary Fig. 18. XPS survey spectrum for aged reference sample.

Supplementary Fig. 19. XPS spectra of the bottom interface before aging and after aging.

**Supplementary Fig. 20. Derivative of X-ray absorption coefficient** in the Sn K-edge region for the MPP and thermal aging samples, as well as SnO<sub>2</sub> and SnI<sub>2</sub> references.
